ENCYCLOPÆDIA BRITANNICA.

PHY—PHY

PHYLACTERY (φυλακτήριον) is the name given in the New Testament to the תפילין (tefillin) or "prayer-thongs" of the Jews. Every Jew wears at prayer two of these thongs—(1) the hand-tefilla, a leather thong wound round the left arm and supporting a small case containing a parchment strip with the passages Exod. xiii. 1-10, 11-16, Deut. vi. 4-9, xi. 13-21 written in four columns; (2) the head-tefilla, a similar thong with the four passages inscribed on four separate slips of parchment, and worn round the head so that the box with the texts rests on the forehead. The use of these phylacteries is justified by a literal interpretation of expressions in the passages above cited, and they form, together with the ציצית (zizith) or "fringe" (Numb. xv. 37 *sq.*) and the mezûza above the door, the three sets of visible signs by which the Israelite is constantly reminded of his duty to God. The zizith is no longer placed on the outer garment as in New Testament times (Matt. xxiii. 5), but on the woollen scarves called תלית (tallith), of which the Jewish man always wears one, while another is wound round the head and neck during prayer. The mezûza is now a longish box fixed over the right doorpost of houses or rooms and containing a parchment with Deut. vi. 4-9, xi. 13-21.

In their origin there can be little doubt that the phylacteries are, according to the proper sense of the Greek word, a kind of amulet, not essentially different from the Aramaic *kme's*, and in fact "the Hebrew" of the Hexapla uses the word "phylacteries" for the amulets (*M. V.* pillows) of Ezek. xiii. 18. Phylactery and mezûza were supposed to keep off hurtful demons (Targ. on Cant. viii. 3). For further particulars, see Surenhusius, *Mishna*, i. 9 *sq.*, and Bodenschatz, *Kirch. Verf. d. heutigen Juden*, iv. 9 *sq.*

PHYLLXERA. See VINE.

PHYSICAL CONSTANTS. See WEIGHTS AND MEASURES.

PHYSICAL GEOGRAPHY. See vol. x. pp. 210-212.

PHYSICAL SCIENCES.¹ According to the original meaning of the word, physical science would be that knowledge which is conversant with the order of nature—that is, with the regular succession of events whether

mechanical or vital—in so far as it has been reduced to a scientific form. The Greek word "physical" would thus be the exact equivalent of the Latin word "natural." In the actual development, however, of modern science and its terminology these two words have come to be restricted each to one of the two great branches into which the knowledge of nature is divided according to its subject-matter. Natural science is now understood to refer to the study of organized bodies and their development, while physical science investigates those phenomena primarily which are observed in things without life, though it does not give up its claim to pursue this investigation when the same phenomena take place in the body of a living being. In forming a classification of sciences the aim must be to determine the best arrangement of them in the state in which they now exist. We therefore make no attempt to map out a scheme for the science of future ages. We can no more lay down beforehand the plan according to which science will be developed by our successors than we can anticipate the particular discoveries which they will make. Still less can we found our classification on the order in time according to which different sciences have been developed. This would be no more scientific than the classification of the properties of matter according to the senses by which we have become acquainted with their existence.

It is manifest that there are some sciences, of which we may take arithmetic as the type, in which the subject-matter is abstract, capable of exact definition, and incapable of any variation arising from causes unknown to us which would in the slightest degree alter its properties. Thus in arithmetic the properties of numbers depend entirely on the definitions of these numbers, and these definitions may be perfectly understood by any person who will attend to them. The same is true of theoretical geometry, though, as this science is associated in our minds with practical geometry, it is difficult to avoid thinking of the probability of error arising from unknown causes affecting the actual measurement of the quantities. There are other sciences, again, of which we may take biology as the type, in which the subject-matter is concrete, not capable of exact definition, and subject to the influence of many causes quite unknown to us. Thus in

¹ The paper of the late Professor J. Clerk Maxwell which is presented to the reader under this head was prepared at the time when the ninth edition of the *Encyclopædia Britannica* was being planned, and bore in his MS. the title "Remarks on the Classification of the Physical Sciences."

biology many abstract words such as "species," "generation," &c., may be employed, but the only thing which we can define is the concrete individual, and the ideas which the most accomplished biologist attaches to such words as "species" or "generation" have a very different degree of exactness from those which mathematicians associate, say, with the class or order of a surface, or with the umbilical generation of conicoids. Sciences of this kind are rich in facts, and will be well occupied for ages to come in the co-ordination of these facts, though their cultivators may be cheered in the meantime by the hope of the discovery of laws like those of the more abstract sciences, and may indulge their fancy in the contemplation of a state of scientific knowledge when maxims cast in the same mould as those which apply to our present ideas of dead matter will regulate all our thoughts about living things.

What is commonly called "physical science" occupies a position intermediate between the abstract sciences of arithmetic, algebra, and geometry and the morphological and biological sciences. The principal physical sciences are as follows.

A. *The Fundamental Science of Dynamics, or the doctrine of the motion of bodies as affected by force.*—The divisions of dynamics are the following. (1) Kinematics, or the investigation of the kinds of motion of which a body or system of bodies is capable, without reference to the cause of these motions. This science differs from ordinary geometry only in introducing the idea of motion,—that is, change of position going on continuously in space and time. Kinematics includes, of course, geometry, but in every existing system of geometry the idea of motion is freely introduced to explain the tracing of lines, the sweeping out of surfaces, and the generation of solids. (2) Statics, or the investigation of the equilibrium of forces,—that is to say, the conditions under which a system of forces may exist without producing motion of the body to which they are applied. Statics includes the discussion of systems of forces which are equivalent to each other. (3) Kinetics, or the relations between the motions of material bodies and the forces which act on them. Here the idea of matter as something capable of being set in motion by force, and requiring a certain force to generate a given motion, is first introduced into physical science. (4) Energetics, or the investigation of the force which acts between two bodies or parts of a body, as dependent on the conditions under which action takes place between one body or part of a body and another so as to transfer energy from one to the other.

The science of dynamics may be divided in a different manner with respect to the nature of the body whose motion is studied. This forms a cross division. (1) Dynamics of a particle; including its kinematics or the theory of the tracing of curves, its statics or the doctrine of forces acting at a point, its kinetics or the elementary equations of motion of a particle, and its energetics, including, as examples, the theory of collision and that of central forces. (2) Dynamics of a connected system, including the same subdivisions. This is the most important section in the whole of physical science, as every dynamical theory of natural phenomena must be founded on it. The subdivisions of this, again, are—*a.* dynamics of a rigid system, or a body of invariable form; *b.* dynamics of a fluid, including the discussion (*a*) of its possible motion, (*b*) of the conditions of its equilibrium (hydrostatics), (*c*) of the action of force in producing motion (hydrodynamics, not so unsatisfactory since Helmholtz, Stokes, and Thomson's investigations), and (*d*) of the forces called into play by change of volume; *c.* dynamics of an elastic body; *d.* dynamics of a viscous body.

B. *The Secondary Physical Sciences.*—Each of these

sciences consists of two divisions or stages. In the elementary stage it is occupied in deducing from the observed phenomena certain general laws, and then employing these laws in the calculation of all varieties of the phenomena. In the dynamical stage the general laws already discovered are analysed and shown to be equivalent to certain forms of the dynamical relations of a connected system (*A*, 2), and the attempt is made to discover the nature of the dynamical system of which the observed phenomena are the motions. This dynamical stage includes, of course, several other stages rising one above the other; for we may successfully account for a certain phenomenon, say the turning of a weathercock towards the direction of the wind, by assuming the existence of a force having a particular direction and tending to turn the tail of the cock in that direction. In this way we may account not only for the setting of the weathercock but for its oscillations about its final position. This, therefore, is entitled to rank as a dynamical theory. But we may go on and discover a new fact, that the air exerts a pressure and that there is a greater pressure on that side of the cock on which the wind blows. This is a further development of the theory, as it tends to account for the force already discovered. We may go on and explain the dynamical connexion between this inequality of pressure and the motion of the air regarded as a fluid. Finally, we may explain the pressure of the air on the hypothesis that the air consists of molecules in motion, which strike against each other and against the surface of any body exposed to the air.

The dynamical theories of the different physical sciences are in very different stages of development, and in almost all of them a sound knowledge of the subject is best acquired by adopting, at least at first, the method which we have called "elementary,"—that is to say, the study of the connexion of the phenomena peculiar to the science without reference to any dynamical explanations or hypotheses. Thus we have—

(1) Theory of gravitation, with discussion of the weight and motion of bodies near the earth, of the whole of physical astronomy, and of the figure of the earth. There is a great deal of dynamics here, but we can hardly say that there is even a beginning of a dynamical theory of the method by which bodies gravitate towards each other.

(2) Theory of the action of pressure and heat in changing the dimensions and state of bodies. This is a very large subject and might be divided into two parts, one treating of the action of pressure and the other of heat. But it is much more instructive to study the action of both causes together, because they produce effects of the same kind, and therefore mutually influence each other. Hence the term "thermodynamics" might be extended to the whole subject were it not that it is already restricted to a very important department relating to the transformation of energy from the thermal to the mechanical form and the reverse. The divisions of the subject are seven. (*a*) Physical states of a substance,—gaseous, liquid, and solid; elasticity of volume in all three states; elasticity of figure in the solid state; viscosity in all three states; plasticity in the solid state; surface-tension, or capillarity; tenacity of solids; cohesion of liquids; adhesion of gases to liquids and solids. (*b*) Effects of heat in raising temperature, altering size and form, changing physical state. (*c*) Thermometry. (*d*) Calorimetry. (*e*) Thermodynamics, or the mutual convertibility of heat and work. (*f*) Dissipation of energy by diffusion of matter by mixture, diffusion of motion by internal friction of fluids, diffusion of heat by conduction. (*g*) Theory of propagation of sound, vibrations of strings, rods, and other bodies.

(3) Theory of radiance. (*a*) Geometrical optics; theory of conjugate foci and of instruments. (*b*) Velocity

of light in different media. (c) Prismatic analysis of light,—spectroscopy, radiant heat, visible radiance, ultra-violet rays, calorescence, &c., fluorescence, &c. (d) Colours of thin plates, diffraction, &c. (d') Proof of the existence of wave-lengths and wave-periods (preparation for dynamical theory). (e) Polarized light, radiant heat, &c. (e') The disturbance is transverse to the ray. (f) Quantity of energy in the total radiation from a hot body; Prévost's theory of exchanges, &c. (g) Theory of three primary colours.

(4) Electricity and magnetism. (a) Electrostatics, or distribution and effects of electricity in equilibrium. (b) Electrokinematics, or distribution of currents in conductors. (c) Magnetism and magnetic induction (diamagnetism, &c.). (d) Electromagnetism, or the effects of an electric current at a distance. Under (b) we may discuss electrochemistry, or the theory of electrolysis; under (c) terrestrial magnetism and ship's magnetism; and after (d) comes electrokinetics, or electromagnetic phenomena considered with reference to the fundamental science of dynamics. There is also Faraday's discovery of the effect of magnetism on light and the electromagnetic theory of light.

Chemistry is not included in this list, because, though dynamical science is continually reclaiming large tracts of good ground from the one side of chemistry, chemistry is extending with still greater rapidity on the other side into regions where the dynamics of the present day must put her hand upon her mouth. Chemistry, however, is a physical science, and a physical science which occupies a very high rank.

(J. C. M.)

PHYSIOGNOMY. By the Act of Parliament 17 George II. c. 5 all persons pretending to have skill in physiognomy were deemed rogues and vagabonds, and were liable to be publicly whipped, or sent to the house of correction until next sessions.¹ The pursuit thus stigmatized as unlawful is one of great antiquity, and one which in ancient and mediæval times had an extensive though now almost forgotten literature. Physiognomy was regarded by those who cultivated it as a twofold science—(1) a mode of discriminating character by the outward appearance and (2) a method of divination from form and feature. It was very early noticed that the good and evil passions by their continual exercise stamp their impress on the face, and that each particular passion has its own expression. Thus far physiognomy is a branch of physiology, and from a very early age of human thought it attracted philosophic attention. But in its second aspect it touched astrology, of which Galen² says that the physiognomical part is the greater, and this aspect of the subject bulked largely in the fanciful literature of the Middle Ages.

The name originated with the Greeks, who called it *φυσιογνωμία*, *φυσιογνωμονία*, or *φυσιογνωμοσύνη*. According to Principal Blackwell³ of Aberdeen, Homer wrote upon the lines of the hand; but this is not supported by classical authority. That Homer was a close observer of appearance as correlated with character is shown in his description of Thersites⁴ and elsewhere. Hippocrates, writing about 450 B.C., refers to this subject, but not in

detail.⁵ He believed in the influence of environment in determining disposition, and in the reaction of these upon feature,—a view in which he is supported later by Trogus. Galen speaks of it at more length in his work *Περὶ τῶν τῆς ψυχῆς ἰθύνων*, in which, having discussed the nature and immortality of the soul, he proceeds in chapter vii. to a brief study of physiognomy (ed. Kühn, iv. 795). However, at the end of the chapter he passes over the current physiognomical speculations, saying that he might criticize them but feared to waste time, and become tedious over them. In the eighth chapter he quotes with approbation the Hippocratic doctrine referred to above; and in a later work, *Περὶ κατακλίσεως προγνωστικά*, he speaks of its relations to medicine thus: "Hippocrates igitur, et vetustate admodum notus et scientia admirandus, inquit, 'quocunque exercentes medicinam, physiognomoniam sunt expertes, horum mens in tenebras devoluta torpida senescit,'" &c.⁶ We learn both from Iamblichus⁷ and Porphyry⁸ that Pythagoras was in the habit of diagnosing the characters of candidates for pupilage before admitting them. However, he seems to have discredited the current physiognomy of the schools, as he rejected Cylo the Crotonian from his discipleship on account of his professing these doctrines, and thereby was brought into considerable trouble.⁹ Plato also tells us that Socrates predicted the promotion of Alcibiades from his appearance; and Apuleius¹⁰ speaks of Socrates recognizing the abilities of Plato at first view. On the other hand, it has been recorded by Cicero¹¹ that a certain physiognomist, Zopyrus, who professed to know the habits and manners of men from their bodies, eyes, face, and forehead, characterized Socrates as stupid, sensual, and dull (*bardus*), "in quo Alcibiades cachinnum dicitur sustulisse." Alexander Aphrodisiensis¹² adds that, when his disciples laughed at the judgment, Socrates said it was true, for such had been his nature before the study of philosophy had modified it. Zopyrus is also referred to by Maximus Tyrius¹³ as making his recognitions "intuitu solo."

That one's occupation stamps its impress on the outward appearance was also noticed at an early period. In the curious poem in praise of literature found in the Sallier papyrus (II.) in the British Museum this is expatiated on, and the effects of divers handicrafts on the workmen are compared with the elevating influences of a literary life by an Egyptian scribe of the XIIth Dynasty, perhaps 2000 years B.C.¹⁴ Josephus tells us that Cæsar detected the pretence of the spurious Alexander by his rough hands and surface.¹⁵

The first systematic treatise which has come down to us is that attributed to Aristotle,¹⁶ in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness,

⁵ *Περὶ ἀέρων, ὕδατων, τόπων* (ed. Kühn, i. 547).

⁶ *Op. cit.*, xix. p. 530.

¹⁴ *Select Papyri*, pl. xv., xix., and (Anastasi) *ibid.*, cxxviii. cxxxi.

¹⁵ *Ant.*, xvii. 12, 2.

¹⁶ Authors differ in their views as to its authenticity, but Diogenes Laertius (v. 22) and Stobæus (*Serm.*, clxxxix.) both believe it to be genuine. The chief difficulty is the reference to a certain sophist, Dionysius, but this is probably an interpolation. There are physiognomic references in other writings of Aristotle (cf. *Anal. pr.*, ii. c. 30; *Hist. anim.*, i. 3, &c.) sufficient to justify the attribution of the treatise to him. On this, see Franz, Preface, p. vi. sq., of his *Scriptores physiognomiae veteres*, Leipsic, 1780.

¹ The Act 39 Elizabeth c. 4 declared "all persons feynung to have knowledge of Physiognomie or like Fantasticall Ymaginacions" liable to "be stripped naked from the middle upwards and openly whipped until his body be bloudey." This was modified by 13 Anne c. 26, still further by 17 George II. c. 5, which was re-enacted by 5 George IV. c. 83. This last Act only specifies palmistry.

² Galen, *Περὶ κατακλίσεως προγνωστικά* (ed. Kühn, xix. 530).

⁴ *Il.*, ii. 214. See also Blackwell's *Inquiry*, 2d ed., 1786, p. 330. A physiognomical study of the Homeric heroes is given by Malalas, *Chronogr.*, ed. Dindorf, v. p. 105.

of genius and stupidity, of timidity, impudence, anger, and their opposites, &c. Then he studies the physiognomy of the sexes, and the characters derived from the different features, and from colour, hair, body, limbs, gait, and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lion-like; slender hooked noses to the eagle-like, the noble but grasping; round-tipped retroussé noses to the luxurious, like barn-door fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares to deer; open nostrils are signs of passion, &c. Several good editions have been published,¹ and numerous voluminous commentaries written upon it;² most subsequent authors have copied from it, with or without acknowledgment. References exist to a work on physiognomy by Theophrastus, but it is not extant; and the next important author is Melampus, the Egyptian hierogrammateus, who lived at the court of Ptolemy Philadelphus, and wrote, about 270 B.C., the work *Περὶ παλμῶν μαντική*. This, while descriptive, like that of Aristotle, deals largely in omens, in divination from nævi and the twitchings of limbs. It was edited by Camillus Peruscius, and published at Rome (1545) along with those of Polemon and Adamantius.³ References to physiognomy are to be found in many of the Greek classics.⁴ Apion speaks of the metoposcopists who judge by the appearance of the face, and Cleanthes the Stoic says it is possible to tell habits from the aspect (cf. *Ecclus.* xix. 29, 30). Polemon (c. 150 A.D.) is the next in order who has left a treatise on the subject, similar in character to that of Aristotle; but he excels in graphic descriptions of different dispositions and differs only from Aristotle in some of his animal comparisons. The best modern edition of his work is contained in Franz's *Scriptores physiognomiae veteres*. It was translated into Latin and published at Venice by Nicholas Petreius in 1534. This book was referred to by Albertus Magnus, who attributes to its author a second work on the subject. A more important contribution to the literature of physiognomy was added by a converted Jew, Adamantius, about 415. This work is in two books, the first on the expression of the eye, the second on physiognomy in general, mostly Aristotelian in character. He professes to have learned much from the Egyptians, and tells us that nature speaks in the forehead and face and in the silence of the mouth. He follows Aristotle in holding rather a low opinion of the intellect of the female sex, whom he makes the subject of some rather depreciating comparisons. His work was edited with the foregoing by Franz.⁵ Artemidorus, Loxus, Philemon, Posidonius,⁶ Con-

stantinus,⁷ are other early authors frequently quoted by 16th-century writers, while Phemonoe, Antiphon, Helenus of Syracuse, and Eumolpius are mentioned as writers by Porta, Albertus Magnus, and others, but their works are not extant.

The Latin classics occasionally refer to physiognomy: Juvenal (vi. 383) speaks of the examination of forehead and face, but not with much respect; Suetonius (*Vita Titi*, 2) tells us, "Quo quidem tempore, aiunt, metoposcopus a Narcisso, Claudio liberto, adhibitum, ut Britannicus inspiceret"; and Pliny also refers to it (*H. N.*, xxxv. 10). References also exist in the writings of Clement of Alexandria; and Origen,⁸ while speaking of the Jewish fable as to the birth of Christ, asks, Is it possible, if there be any truth in the science taught by Zopyrus, Loxus, and Polemon, that such a soul as Christ's could have been provided with a suitable body in such a way? Sir George Wharton quotes the text Job xxxvii. 7, "He impresseth (חַתְמוֹתָיו) the hand of every man, that all may know His work," as an authority for chiromancy, and other chiromantists have followed him in so doing.⁹

Hitherto the physiognomy of the schools had been chiefly descriptive; in the succeeding period the astrological side, whose gradual development may be noted, becomes the most important part. Hence in the subsequent or second stage of history chiromancy is specially predictive in character, and attains an importance it had not originally possessed. The treatises also contain occasional digressions on onychomancy, alectoromancy, clidomancy, coccinomancy, podoscopy, spasmatomancy, &c.

Along with the medical science of the period the Arabians took up the study of physiognomy: 'Alī b. Ragel wrote a book on nævi; Rhazes (1040) devoted several chapters of his medical work to it; and Averroes (1165) made many references to it in his *De Sanitate* (p. 82, Leyden, 1537). Avicenna also makes some acute physiognomical remarks in his *De Animalibus*, which was translated by Michael Scott about 1270, but printed subsequently (without date or place). Albertus Magnus (born 1205) devotes much of the second tract of his *De Animalibus* to the consideration of physiognomy. There is, however, nothing original in the treatise, which largely consists of extracts from Aristotle, Polemon, and Loxus. He does not enter so much into the animal comparisons of his predecessors, but occupies himself chiefly with simple descriptive physiognomy as indicative of character; and the same is true of the many scattered notes in the writings of Duns Scotus and Thomas Aquinas. The famous sage of Balwearie, Michael Scott, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisionomia* (c. 1272), much of which is physiological and of curious interest. It was not printed until 1477, and the edition was not illustrated. The physiognomical treatise forms the third part of his work *De secretis naturæ*. In 1335 Petrus de Abano of Padua delivered in Paris a course of lectures on this subject (afterwards edited by Blondus, 1544), a few years before he was burned for heresy. Shortly after the introduction of printing in the 15th century a large number of works on physiognomy were produced; probably the oldest is the block book by Hartlieb, *Die Kunst Ciromantia*. This is an exceedingly rare folio, of which one fine copy is extant in Paris; each page bears a figure of a giant hand from 7 to 10½ inches long, inscribed with characteristic words, and with a small amount of description below; there are twenty-seven such

¹ That of J. G. Franz (Leipzig, 1780) is the best; Andreas Lacuna published a Latin version, Paris, 1535; Willichius, another at Wittenberg, 1538.

² Fontain's *Commentary* (Paris, 1611), Camillus Baldus of Bologna (1621), Sanchez of Toulouse (1636).

³ And later by Franz (*op. cit.*, p. 470).

⁴ See an interesting paper on "Stretching and Yawning as Signs of Madness," by Professor Ridgeway (*Trans. Camb. Philol. Soc.*, vol. i. p. 210), which refers to Aristoph., *Wasps*, 642, with which he compares Plautus, *Menæchmi*, 279. Other references exist to physiognomy in Cassiodorus, Isidorus, Meletius, and Nemesius, but none of any very great importance.

⁵ It was edited by Janus Cornaro at Marburg, 1543, by Bonum of Paris ten years later, by Camillus Peruscius, by Petreius, and by Sylburg in the sixth volume of his *Aristotle*.

⁶ *Περὶ παλμῶν*. See Justin Martyr's *Quest. ad orthodox.*, xix., vol. ii., Paris, 1742, p. 461.

⁷ Constantinus Africanus, *De humana natura et principalibus membris corporis humani*, Basel, 1541, folio.

⁸ *Contra Celsum*, i. 33.

⁹ For other references to Scriptural allusions to physiognomy, see Vecchius, *Observationes in div. script.*, Naples, 1641.

plates. A description of another perfect copy belonging to Earl Spencer occurs in Dibdin's *Bibliographical De-cameron* (1817), vol. i. p. 143, and four imperfect copies are known to exist elsewhere. The date of Hartlieb's work is probably 1470. This and Michael Scott's books were the first printed works on the subject.

The 16th century was particularly rich in publications on physiognomy. Not only were the classical works printed, but additions were made to the literature by Cocles, Corvus, Johannes de Indagine, Cornaro, Blondus, Douxciel, Pompeius Ronseus, Gratarolus, Niquetius, Pomponius Gauricus, Tricassus, Cardan, Tiberius, Thaddæus ab Hayck, Taisnierus, Rizzacasa, Campanella, Hund, Picciolus, Rothman, Johannes Padovanus, and, last and greatest of all, Giambattista della Porta. Several works also appeared in England, the earliest being the anonymous *On the Art of foretelling Future Events by Inspection of the Hand* (London, 1504). A second anonymous work, *A pleasant Introduction to the Art of Chiromancie and Physiognomie*, was published at the same place in 1558. Neither of these is of any merit. The first English work with the author's name is that of Dr Thomas Hill (1571), *The Contemplation of Mankynde, contayning a singular Discourse after the Art of Physiognomie*. This is rather quaintly written, but is simply an adaptation from the Italian writers of the day. Another anonymous author about this period, but whose work has no date, writes, under the name "Merlin Britannicus," upon moles and naevi after the model of 'Alī b. Ragel. The word "physiognomy" had been introduced into England before this century, and, from analogy with the Greek, had been used in the sense of the outward appearance, or the face: thus in Udall's translation of the paraphrase of Erasmus on Mark iv. it occurs spelt "phisnomi"; the pugnacious bishop of Ossory, Bale, in his *English Votaries*, spells it "phynomie" (pt. i. ch. ii. p. 44).

The rise of the study of anatomy served largely to bring physiognomy into discredit by substituting real facts for fictions; hence in the 17th century its literature, while not smaller in quantity, was less important in quality. The principal authors are Goclenius, Fuchs, Timpler, Tischbein, Gallimard, Moldenarius, Septalius, Hertod, Scarlatini, Saunders, Withers, Helvetius, Lebrun, Elsholtius, De la Bellière, Philipp May, Evelyn, Freius, Baldus, Torreblanca, Otto, Bulwer, Rhyne, Merbitzius, Fludd, Zanardus, Finella, Tamburini, Etzler, Vecchius, Prætorius, De la Chambre, and Giraldu.

The 18th century shows a still greater decline of interest in physiognomy. Historians of philosophy, like Meursius and Franz, re-edited some of the classical works, and Fülleborn reviewed the relation of physiognomy to philosophy. Indeed the only name worthy of note is that of LAVATER (*q.v.*). The other authors of this century are Penschel, Spon, Lichtenberg, Schutz, Wegelin, Pernetty, Hirtanner, Grohmann, and several anonymous writers, and from the anatomical side Lancisi, Parsons, and Peter Camper. The popular style, good illustrations, and pious spirit pervading the writings of Lavater have given to them a popularity they little deserved, as there is really no system in his work, which largely consists of rhapsodical comments upon the several portraits. Having a happy knack of estimating character, especially when acquainted with the histories of the persons in question, the good pastor contrived to write a graphic and readable book, but one much inferior to Porta's or Aristotle's as a systematic treatise. With him the descriptive school of physiognomists may be said to have ended, as the astrological physiognomy expired with De la Bellière. The few straggling works which have since appeared are scarcely deserving of notice, the rising attraction of phrenology having given to pure physiognomy the *coup de grâce* by taking into itself whatever

was likely to live of the older science. The writers of this century are Hörstig, Maas, Rainer, Cross, Stöhr, Sehler, Diez, Carus, Piderit, Burgess, and Gratiolet.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, as his *Essay on the Anatomy of Expression*, published in 1806, was the first really scientific study of expression. He was one of the first who accurately correlated the motions expressive of the passions with the muscles which produce them, and in the later editions of his work these descriptions are much enlarged and improved. Shortly after the appearance of the first edition of Bell's *Essay* Moreau published his first edition of Lavater along somewhat the same lines (1807). The experiments of Duchenne (*Mécanisme de la Physionomie Humaine*, Paris, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These tested and confirmed by experimental demonstration the hypothetic conclusions of Bell. The machinery of expression having thus been clearly followed out, the correlation of the physical actions and the psychical states was made the subject of speculation by Spencer (*Psychology*, 1855), and such speculations were first reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated and illustrated the following as fundamental principles.

(1) Certain complex acts are of direct or indirect service under certain conditions of the mind in order to relieve or gratify certain sensations or desires; and whenever the same state of mind is induced the same set of actions tend to be performed, even when they have ceased to be of use. (2) When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. (3) When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connexions of nerve-cells and on habit.

It follows from these propositions that the expression of emotion is for the most part not under the control of the will, and that those striped muscles are the most expressive which are the least voluntary. The philosophy of physiognomy may be formulated upon this definite theoretic basis. (1) The actions we look upon as expressive of emotions are such as at some time were serviceable in relieving or gratifying the desires or sensations accompanying the emotion. (2) Such actions become habitually associated with the mental condition and continue even where their utility is lost. (3) Certain muscles which produce these actions become from habitual action strengthened, and, when the skin diminishes in fulness and elasticity with advancing age, the action of the muscle produces furrows or wrinkles in the skin at right angles to the course of the fibres of the muscle. (4) As the mental disposition and proneness to action are inherited by children from parents, so the facility and proneness to expression are similarly developed under the law of heredity. (5) To some extent habitual muscular action and the habitual flow of nerve-force in certain directions may alter the contour of such bones and cartilages as are thereby acted upon by the muscles of expression. Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne, and Darwin, to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy see the catalogue of sixty-two authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, &c., Leipzig, 1852, and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Cardan, Corvus, and Bulwer. An attempt has been made recently to rehabilitate palmistry by D'Arpentigny and Desbarrolles, for summaries of which see the works of Beamish and Craig. For physiognomy of disease, besides the usual medical handbooks, see Cabuchet, *Essai sur l'Expression de la Face dans les Maladies*, Paris, 1801. For ethnological physiognomy, see amongst older authors Gratarolus, and amongst moderns the writers cited in the various text-books on anthropology. (A. MA.)

PHYSIOLOGUS, the most common title of a collection of some fifty Christian allegories much read in the Middle Ages, and still existing in several forms and in about a dozen Eastern and Western languages. As nearly all its imagery is taken from the animal world, it is also known as the *Bestiary*. There can be hardly a doubt about the time and general circumstances of its origin. Christian teachers, especially those who had a leaning towards gnostic speculations, took an interest in natural history, partly because of certain passages of Scripture that they wanted to explain, and partly on account of the divine revelation in the book of nature, of which also it was man's sacred duty to take proper advantage. Both lines of study were readily combined by applying to the interpretation of descriptions of natural objects the allegorical method adopted for the interpretation of Biblical texts. Now the early Christian centuries were anything but a period of scientific research. Rhetorical accomplishments were considered to be the chief object of a liberal education, and to this end every kind of learning was made subservient. Instead of reading Aristotle and other naturalists, people went for information to commonplace books like those of Ælian, in which scraps of folk-lore, travellers' tales, and fragments of misapprehended science were set forth in an elegant style for the enjoyment of the general reader. Theological writers with a merely literary training were not in the least prepared to question the worth of the marvellous descriptions of creatures that were current in the schools on the faith of authorities vaguely known as "the history of animals," "the naturalists," and "the naturalist" in the singular number (*φυσιολόγος*).¹ So they took their notions of strange beasts and other marvels of the visible world on trust and did their best to make them available for religious instruction. In some measure we find this practice adopted by more than one of the fathers, but it was only natural that the Alexandrian school, with its pronounced taste for symbolism, should make the most of it. Clement himself had declared that natural lore, as taught in the course of higher Christian education according to the canon of truth, ought to proceed from "cosmogony" to "the theological idea,"² and even in the little that is left of the works of Origen we have two instances of the proceeding in question. And yet the fact that these reappear in the *Physiologus* would not suffice to stamp the work as a series of extracts from Alexandrian writings, as parallels of the same kind can be adduced from Epiphanius (*loc. cit.*) and Ephraem Syrus (*Opp. Syr.*, ii. pp. 17, 130). Father Cahier would even trace the book to Tatian, and it is true that that heresiarch mentions a writing of his own upon animals. Still the context in which the quotation occurs makes it evident that the subject-matter was not the nature of particular species nor the spiritual lessons to be drawn therefrom, but rather the place occupied by animal beings in the system of creation. On the other hand, the opinion of Cardinal Pitra, who referred the *Physiologus* to the more orthodox though somewhat peculiar teaching of the Alexandrians, is fully borne out by a close examination of the irregularities of doctrine pointed out in the *Physiologus* by Cahier, all of which are to be met with in Origen. The technical words by which the process of allegorizing is designated in the *Physiologus*, like *ἐρμηνεία*, *θεωρία*, *ἀναγωγή*, *ἀλληγορία*, are familiar to the students of Alexandrian exegesis. It

has, moreover, been remarked that almost all the animals mentioned were at home in the Egypt of those days, or at least, like the elephant, were to be seen there occasionally, whereas the structure of the hedgehog, for instance, is explained by a reference to the sea-porcupine, better known to fish-buyers on the Mediterranean. The fables of the phoenix and of the conduct of the wild ass and the ape at the time of the equinox owe their origin to astronomical symbols belonging to the Nile country.³ In both chapters an Egyptian month is named, and elsewhere the antelope bears its Coptic name of "antholops."

That the substance of the *Physiologus* was borrowed from commentaries on Scripture⁴ is confirmed by many of the sections opening with a text, followed up by some such formula as "but the Physiologus says." When zoological records failed, Egypto-Hellenic ingenuity was never at a loss for a fanciful invention distilled from the text itself, but which, to succeeding copyists, appeared as part of the teaching of the original Physiologus. As a typical instance we may take the chapter on the ant-lion,—not the insect, but an imaginary creature suggested by Job iv. 11. The exceptional Hebrew for a lion (*layish*) appeared to the Septuagint translators to call for a special rendering, and as there was said to exist on the Arabian coast a lion-like animal called "myrmex" (see Strabo, xvi. p. 774; Ælian, *N. A.*, vii. 47) they ventured to give the compound noun "myrmekoleon." After so many years the commentators had lost the key to this unusual term, and only knew that in common Greek "myrmex" meant an ant. So the text "the myrmekoleon hath perished for that he had no nourishment" set them pondering, and others reproduced their meditations, with the following result: "The *Physiologus* relates about the ant-lion: his father hath the shape of a lion, his mother that of an ant; the father liveth upon flesh, and the mother upon herbs. And these bring forth the ant-lion, a compound of both, and in part like to either, for his fore part is that of a lion, and his hind part like that of an ant. Being thus composed, he is neither able to eat flesh like his father, nor herbs like his mother; therefore he perisheth from inanition"; the moral follows.

At a later period, when the church had learnt to look with suspicion upon devotional books likely to provoke the scoffing of some and lead others into heresy, a work of this kind could hardly meet with her approval. A synod of Pope Gelasius, held in 496, passed censure, among others, on the "Liber Physiologus, qui ab hæreticis conscriptus est et B. Ambrosii nomine signatus, apocryphus," and evidence has even been offered that a similar sentence was pronounced a century before. Still, in spite of such measures, the *Physiologus*, like the *Church History* of Eusebius or the *Pastor of Hermas*, continued to be read with general interest, and even Gregory the Great did not disdain to allude to it on occasion. Yet the Oriental versions, which had certainly nothing to do with the Church of Rome, show that there was no systematic revision made according to the catholic standard of doctrine. The book remained essentially the same, albeit great liberties were taken with its details and outward form. There must have been many imperfect copies in circulation, from which people transcribed such sections as they found or chose, and afterwards completed their MS. as occasion served. Some even rearranged the contents according to the alphabet or to zoological affinity. So little was the collection considered as a literary work with a definite text that every one assumed a right to abridge or enlarge, to insert ideas of his

¹ Origen, *Sel. in Jerem.*, xvii. 11, "ἐν τῇ περὶ ζώων ιστορίᾳ"; Epiphanius, *Adv. Hær.*, i. 3, p. 274 (ed. D. Petav.), "ὡς φασιν οἱ φυσιολόγοι"; Origen, *Hom.* xvii., in Gen. xiv. 9, "nam physiologus de catulo leonis scribit."

² *Strom.*, iv. p. 564 (ed. Potter), ἡ γοῦν κατὰ τὸν τῆς ἀληθείας κανόνα γνωστικῆς παραδόσεως φυσιολογία, μᾶλλον δὲ ἐποπτεία, ἐκ τοῦ περὶ κοσμογονίας ἡρηται λόγου, ἐνθένδε ἀναβαίνουσα ἐπὶ τὸ θεολογικὸν εἶδος.

⁴ Including the Apocrypha. See the Icelandic account of the elephant, also a decidedly Alexandrian fragment upon the *μάργος*, founded upon 4 Maccab. i. 3, which has got into the scholia upon the *Odyssey*, xviii. 2 (ii. p. 533, ed. Dindorf, Oxford, 1855).

own, or fresh Scriptural quotations; nor were the scribes and translators by any means scrupulous about the names of natural objects, and even the passages from Holy Writ. *Physiologus* had been abandoned by scholars, and left to take its chance among the tales and traditions of the uneducated mass. Nevertheless, or rather for this very reason, its symbols found their way into the rising literature of the vulgar tongues, and helped to quicken the fancy of the artists employed upon church buildings and furniture.

The history of the *Physiologus* has become entwined from the beginning with that of the commentaries on the account of creation in Genesis. The principal production of this kind in our possession is the *Hexameron* of Basil, which contains several passages very like those of the *Physiologus*. For instance, in the seventh homily the fable of the nuptials of the viper and the conger-eel, known already to *Ælian* and *Oppian*, and proceeding from a curious misreading of Aristotle (*Hist. An.*, v. 4, p. 540 b, Bekk.), serves to point more than one moral. Notwithstanding the difference in theology, passages of this kind could not but be welcome to the admirers of the Alexandrian allegories. In fact a medley from both Basil and the *Physiologus* exists under the title of the *Hexameron* of Eustathius; some copies of the first bear as a title *Περὶ φυσιολογίας*, and in a Milan MS. the "morals" of the *Physiologus* are ascribed to Basil. The Leyden Syriac is supplemented with literal extracts from the latter, and the whole is presented as his work. Other copies give the names of Gregory Theologus, Epiphanius, Chrysostom, and Isidore.

As far as can be judged, the emblems of the original *Physiologus* were the following: (1) the lion (footprints rubbed out with tail; sleeps with eyes open; cubs receive life only three days after birth by their father's breath); (2) the sun-lizard (restores its sight by looking at the sun); (3) the charadrius (*Deut.* xiv. 16; presages recovery or death of patients); (4) the pelican (recalls its young to life by its own blood); (5) the owl (or *nyktikorax*; loves darkness and solitude); (6) the eagle (renews its youth by sunlight and bathing in a fountain); (7) the phoenix (revives from fire); (8) the hoopoe (redeems its parents from the ills of old age); (9) the wild ass (suffers no male besides itself); (10) the viper (born at the cost of both its parents' death); (11) the serpent (sheds its skin; puts aside its venom before drinking; is afraid of man in a state of nudity; hides its head and abandons the rest of its body); (12) the ant (orderly and laborious; prevents stored grain from germinating; distinguishes wheat from barley on the stalk); (13) the sirens and onocentaurs (*Isa.* xiii. 21, 22; compound creatures); (14) the hedgehog (pricks grapes upon its quills); (15) the fox (catches birds by simulating death); (16) the panther (spotted skin; enmity to the dragon; sleeps for three days after meals; allures its prey by sweet odour); (17) the sea-tortoise (or *aspidochelone*; mistaken by sailors for an island); (18) the partridge (hatches eggs of other birds); (19) the vulture (assisted in birth by a stone with loose kernel); (20) the ant-lion (able neither to take the one food nor to digest the other); (21) the weasel (conceives by the mouth and brings forth by the ear); (22) the unicorn (caught only by a virgin); (23) the beaver (gives up its testes when pursued); (24) the hyæna (a hermaphrodite); (25) the otter (enhydris; enters the crocodile's mouth to kill it); (26) the ichneumon (covers itself with mud to kill the dragon; another version of No. 25); (27) the crow (takes but one consort in its life); (28) the turtle-dove (same nature as No. 27); (29) the frog (either living on land and killed by rain, or in the water without ever seeing the sun); (30) the stag (destroys its enemy the serpent); (31) the salamander (quenches fire); (32) the diamond (powerful

against all danger); (33) the swallow (brings forth but once; misreading of Aristotle, *Hist. An.*, v. 13); (34) the tree called peridexion (protects pigeons from the serpent by its shadow); (35) the pigeons (of several colours; led by one of them, which is of a purple or golden colour); (36) the antelope (or *hydrissus*; caught by its horns in the thicket); (37) the fire-flints (of two sexes; combine to produce fire); (38) the magnet (adheres to iron); (39) the saw-fish (sails in company with ships); (40) the ibis (fishes only along the shore); (41) the ibex (descries a hunter from afar); (42) the diamond again (read "carbuncle"; found only by night); (43) the elephant (conceives after partaking of mandrake; brings forth in the water; the young protected from the serpent by the father; when fallen is lifted up only by a certain small individual of its own kind); (44) the agate (employed in pearl-fishing); (45) the wild ass and ape (mark the equinox); (46) the Indian stone (relieves patients of the dropsy); (47) the heron (touches no dead body, and keeps to one dwelling-place); (48) the sycamore (or wild fig; grubs living inside the fruit and coming out); (49) the ostrich (devours all sorts of things; forgetful of its own eggs). Besides these, or part of them, certain copies contain sections of unknown origin about the bee, the stork, the tiger, the woodpecker, the spider, and the wild boar.

The Greek text of the *Physiologus* exists only in late MSS., and has to be corrected from the translations. In Syriac we have a full copy in a 12th-century Leyden MS., published in J. P. N. Land's *Anecdota Syriaca*; thirty-two chapters with the "morals" left out in a very late Vatican copy, published by Tychsen; and about the same number in a late MS. of the British Museum (Add. 25878). In Armenian Pitra gave some thirty-two chapters from a Paris MS. (13th century). The *Æthiopic* exists both in London and Paris, and was printed at Leipsic by Dr Hommel in 1877. In Arabic we have fragments at Paris, of which Renan translated a specimen for the *Spicilegium Solesmense*, and another version of thirty-seven chapters at Leyden, probably the work of a monk at Jerusalem, which Land translated and printed with the Syriac. The Latin MSS. of Bern are, after the Vatican glossary of Ansileubus, the oldest of which we know; there are others in several libraries, and printed editions by Mai, Heider, and Cahier. Besides these a few fragments of an old abridgment occur in Vallarsi's edition of Jerome's works (vol. xi. col. 218). A metrical *Physiologus* of but twelve chapters is the work of Theobaldus, probably abbot of Monte Cassino (1022-1035 A.D.). From this was imitated the Old-English fragment printed by Th. Wright, and afterwards by Maetzner; also the Old-French *Sensuyt le bestiaire d'amours*. The prose *Physiologus* was done into Old High German before 1000, and afterwards into rhyme in the same idiom; since Von der Hagen (1824) its various forms have found careful editors among the leading Germanists. The Icelandic, in a Copenhagen MS. of the 13th century, was printed by Prof. Th. Möbius in his *Analecta norroena* (2d ed., 1877); at the same time he gave it in German in Dr Hommel's *Æthiopic* publication. Some Anglo-Saxon metrical fragments are to be found in Grein's *Bibliothek*, vol. i. The Provençal (c. 1250), published in Bartsch's *Christomathie provençale*, omits the "morals," but is remarkable for its peculiarities of form. Before this there had been translations into French dialects, as by Philippe de Thaurin (1121), by Guillaume, "clerc de Normandie," also, about the same period, by Pierre, a clergyman of Picardy. All the Old-French materials have not yet been thoroughly examined, and it is far from improbable that some versions of the book either remain to be detected or are now lost past recovery. A full account of the history of the *Physiologus* should also embrace the subjects taken from it in the productions of Christian art, the parodies suggested by the original work, e.g., the *Bestiaire d'Amour* by Richard de Fournival, and finally, the traces left by it upon the encyclopædical and literary work of the later Middle Ages.

Nearly all the information now obtainable is to be found in the following works, and such as are there quoted: S. *Epiphanius ad Physiologum*, ed. Ponce de Leon, Rome, 1587 (with woodcuts); another edition, Antwerp, 1588 (with copper-plates); S. *Eustathii in Hexameron Commentarius*, ed. Leo Allatius, Lyons, 1629 (cp. H. van Herwerden, *Exercit. Critt.*, Hague, 1862, pp. 180-182); *Physiologus Syrus*, ed. O. G. Tychsen, Rostock, 1795; *Classici Auctores*, ed. Mai, vol. vii., Rome, 1835, pp. 585-596; G. Heider, in *Archiv für Kunde Österreich. Geschichtsquellen*, Vienna, 1850, vol. ii. p. 545 sq.; Cahier and Martin, *Mélanges d'Archéologie*, &c., vol. ii., Paris (1851), p. 85 sq., vol. iii. (1858) p. 208 sq., vol. iv. (1856) p. 55 sq.; Cahier, *Nouveaux Mélanges* (1874) p. 106 sq.; J. B. Pitra, *Spicilegium Solesmense*, vol. iii., Paris, 1855, pp. xlvii. sq., 388 sq., 416, 585; Maetzner, *Altengl. Sprachproben*, vol. i. pt. I., Berlin, 1867, p. 55 sq.; J. Victor Carus, *Gesch. der Zoologie*, Munich, 1872, p. 109 sq.; J. P. N. Land, *Anecdota Syriaca*, vol. iv., Leyden, 1874, p. 81 sq., 115 sq., and in *Verlagen en Mededeelingen der kon. Akad. van Wetenschappen*, 2d series, vol. iv., Amsterdam, 1874; Möbius and Hommel in their publications quoted above. (J. P. N. L.)

PHYSIOLOGY

PART I.—GENERAL VIEW.

THE word "physiology" may be used either in a general or in a more restricted sense. In its more general meaning it was used largely of old, and is still occasionally used in popular writings, to denote all inquiry into the nature of living beings. A very slight acquaintance, however, with the phenomena of living beings shows that these can be studied from two, apparently very different, points of view.

Morpho-
logy.

The most obvious and striking character of a living being is that it appears to be an agent, performing actions and producing effects on the world outside itself. Accordingly, the first efforts of inquirers were directed towards explaining how these actions are carried on, how the effects of a living being upon its surroundings are brought about. And the dissection or pulling to pieces of the material body of a living being was, under the name of ANATOMY (*q.v.*), regarded as simply an analysis preparatory and necessary to the understanding of vital actions. But it soon became obvious that this anatomical analysis gave rise of itself to problems independent of, or having only distant relations to, the problems which had to do with the actions of living beings. Hence in course of time a distinct science has grown up which deals exclusively with the laws regulating the form, external and internal, of living beings, a science which does not seek to explain the actions of living beings, and takes note of these actions only when they promise to throw light on the occurrence of this or that structural feature. Such a science, which is now known under the name of MORPHOLOGY (*q.v.*), might be carried on in a world in which all living things had, in the ordinary meaning of the word, become dead. Were the whole world suddenly petrified, or were a spell to come over it like that imagined by Tennyson in his "Day Dream," but more intense, so that not only the gross visible movements but the inner invisible movements which are at the bottom of growth were all stayed, the morphologist would still find ample exercise for his mind in investigating the form and structure of the things which had been alive, and which still differed from other things in their outward lineaments and internal build.

Physio-
logy de-
fined.

In its older sense physiology embraced these morphological problems, and so corresponded to what is now called BIOLOGY (*q.v.*); in its more modern sense physiology leaves these matters on one side and deals only with the actions of living beings on their surroundings (the study of these necessarily involving the correlative study of the effect of the surroundings on the living being), and appeals to matters of form and structure only so far as they throw light on problems of action. Looking forward into the far future, we may perhaps dimly discern the day when morphology and physiology will again join hands, and all the phenomena of living beings, both those which relate to form and those which relate to action, will be seen to be the common outcome of the same molecular processes. But that day is as yet most distant; and, though occasionally even now the two sciences cross each other's path, action explaining form and form in turn explaining action, the dominant ideas of the two are so distinct, the one from the other, that each must for a long time yet be developed along its own line. It is proposed to treat in the following pages of physiology in this narrower, more restricted sense.

If any one at the present day, making use of the knowledge so far gathered in, were to attempt a rough prelimi-

nary analysis of the phenomena of action of a living being, —for instance of one of the more complex, so-called higher animals, such as man—he might proceed in some such way as the following.

One of the first, perhaps the first and most striking fact about man is that he moves: his body moves of itself from place to place, and one part of the body moves on another. If we examine any one of these movements, such as the bending of the forearm on the arm, we find that it is brought about by certain masses of flesh, called muscles, which from time to time contract, that is, shorten; and these muscles are so disposed that, when they shorten, and so bring their ends nearer together, certain bones are pulled upon and the arm is bent. Upon further examination it will be found that all the gross movements of the body, both the locomotion of the whole body and the movements of parts upon parts, are carried out by the contraction or shortening of muscles. The muscles, together with bones, tendons, and other structures, are arranged in various mechanical contrivances, many of them singularly complex; hence the great diversity of movement of which an animal or man is capable; but in all cases the central fact, that which supplies the motive-power, is the contraction of a muscle, a shortening of its constituent fibres whereby its two ends are brought for a while nearer together.

When, pushing the analysis farther, we attempt to solve the question, Why do muscles contract? we find that the muscles of the body are connected with what is called the central nervous system by certain strands of living matter called nerves; and we further find that, with some few exceptions, which need not concern us now, the contractions of muscles are brought about by certain occult invisible changes called nervous impulses which travel along these nerves from the central nervous system to the muscles. Hence, when a nerve is severed, the muscle to which the nerve belonged, thus cut adrift from the central nervous system, no longer stirred by impulses reaching it from thence, ceases to contract, and remains motionless and as it were helpless. Pushing the problem still farther home, and asking how these impulses originate in the central nervous system, we find that this central nervous mass is connected, not only with the muscles by means of nerves which, carrying impulses outward from itself to the muscles and so serving as instruments of movement, are called motor or efferent nerves, but also with various surfaces and parts of the body by means of other nerves, along which changes or impulses travel inwards to itself in a centripetal fashion. Moreover, the beginnings or peripheral endings of these other nerves appear to be so constituted that various changes in the surroundings of the body, or internal changes in the body itself, give rise to impulses, which, thus originated, travel inwards to the central nervous system; hence these nerves are spoken of as sensory or afferent. Such sensory impulses reaching the central nervous system may forthwith issue as motor impulses leading to movement; but on many occasions they tarry within the central mass, sweeping backwards and forwards along particular areas of its substance, thus maintaining for a while a state of molecular agitation and leading to movement at some subsequent period only. Moreover, we have reason to think that molecular disturbances may arise within the central nervous system apart from the advent, either past or present, of any impulses along sensory nerves. Lastly, the presence of these molecular agitations in the central

nervous system, whether the immediate result of some new afferent impulse, or the much delayed and complicated outcome of some impulse which arrived long ago, or the product of internal changes apparently independent of all disturbance from without and so far spontaneous, may be indicated by corresponding phases of what we speak of as consciousness. We are thus led to conceive of the central nervous system as, chiefly at least, the seat of a molecular turmoil maintained by multitudinous afferent impulses streaming in along the various afferent nerves, a turmoil which makes itself felt within as changes of consciousness, and produces effects without by movements wrought through motor nerves and muscles. And one large part of physiology has for its task the unravelling of the laws which govern this turmoil, which determine, in relation to the advent of afferent impulses and the occurrence of intrinsic changes, the issue of motor impulses, and thus the characters of the resulting movements.

Chemical changes. The movements of man or of an animal are not, however, the only salient facts of his existence. Equally characteristic of him are the facts, (1) that he from time to time eats, and must eat in order to live, and (2) that a supply of fresh air containing a certain quantity of oxygen is indispensable to his remaining alive. Viewed from a chemical point of view, an animal body, whether dead or alive, is a mass of complex unstable chemical substances, combustible in nature, *i.e.*, capable of being oxidized, and of being reduced by oxidation to simpler, more stable substances, with a setting free of energy. Combustible in the ordinary sense of the word an animal body is not, by reason of the large excess of water which enters into its composition; but an animal body thoroughly dried will in the presence of oxygen burn like fuel, and, like fuel, give out energy as heat. The material products of that combustion are fairly simple, consisting of water, carbonic acid, some ammonia or nitrogen compounds, and a few salts. And these same substances appear also as the products of that slower combustion which we call decay; for, whether the body be burnt swiftly in a furnace or rot away slowly in earth, air, or water, the final result is the same, the union of the complex constituent substances with the oxygen furnished from the air, and their reduction thereby to the above-named products, with a development of heat, which either as in the first case is rapid and appreciable, or as in the second is so slow and gradual as to be with difficulty recognized. Moreover, during life also the same conversion, the same oxidation, the same reduction of complex substances to simpler matters, the same setting free of the energy present in the former but absent in the latter, may be noted. The animal body dies daily, in the sense that at every moment some part of its substance is suffering decay, is undergoing combustion; at every moment complex substances full of latent energy are by processes of oxidation reduced to simpler substances devoid of energy or containing but little.

Source of bodily energy. This breaking down of complex substances, this continued partial decay, is indeed the source of the body's energy; each act of life is the offspring of an act of death. Each strain of a muscle, every throb of the heart, all the inner work of that molecular turmoil of the nervous system of which we spoke above, as well as the chemical labour wrought in the many cellular laboratories of glands and membranes, every throw of the vital shuttle, means an escape of energy as some larger compacted molecule splits into smaller simpler pieces. Within the body the energy thus set free bears many shapes, but it leaves the body in two forms alone, as heat and as the work done by the muscles of the frame. All the inner labour of the body, both that of the chemical gland-cells, of the vibrating nerve-substance with its accompanying changes of con-

sciousness, and of the beating heart and writhing visceral muscles, is sooner or later, by friction or otherwise, converted into heat; and it is as heat that the energy evolved in this labour leaves the body. Manifold as seems the body's energy, it has but one source, the decay of living material, *i.e.*, the oxidation of complex substances diversely built up into various living matters, and but two ends, heat and muscular work. The continued setting free of energy which thus marks the living body, entailing as it does the continued breaking up and decay of living substance, constitutes a drain upon the body which must be met by constantly-renewed supplies, or otherwise the body would waste away and its energy flicker out. Hence the necessity on the one hand for that which we call food, which, however varied, is essentially a mixture of complex combustible energy-holding bodies, and on the other hand for that other kind of food which we call breath, and which supplies the oxygen whereby the complex oxidizable substances may be oxidized to simpler matters and their potential energy made to do work. Thus food supplies the energy of the body, but in quantity only, not in quality. The food by itself, the dead food, can exhibit energy as heat only, with intervening phases of chemical action; before its energy can be turned into the peculiar grooves of nervous and muscular action it needs to be transmuted into living substance, and in that transmutation there is a preliminary expenditure of part of the food's store of energy.

Here, then, we have a second view of physiological labour. To the conception of the body as an assemblage of molecular thrills—some started by an agent outside the body, by light, heat, sound, touch, or the like; others begun within the body, spontaneously as it were, without external cause: thrills which, travelling to and fro, mingling with and commuting each other, either end in muscular movements or die away within the body—to this conception we must add a chemical one, that of the dead food continually being changed and raised into the living substance, and of the living substance continually breaking down into the waste matters of the body by processes of oxidation, and thus supplying the energy needed both for the unseen molecular thrills and the visible muscular movements.

Here the problems of physiology may in a broad sense be spoken of as threefold. (1) On the one hand, we have to search the laws according to which the complex unstable food is transmuted into the still more complex and still more unstable living flesh, and the laws according to which this living substance breaks down into simple, stable waste products, void or nearly void of energy. (2) On the other hand, we have to determine the laws according to which the vibrations of the nervous substance originate from extrinsic and intrinsic causes, the laws according to which these vibrations pass to and fro in the body acting and reacting upon each other, and the laws according to which they finally break up and are lost, either in those larger swings of muscular contraction whereby the movements of the body are effected, or in some other way. (3) And lastly, we have to attack the abstruser problems of how these neural vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous and muscular substances, that is, of how the energy of chemical action is transmuted into and serves as the supply of that vital energy which appears as movement, feeling, and thought.

Even a rough initial analysis, however, such as we have just attempted to sketch, simple as it seems with our present knowledge, is an expression of the accumulated and corrected inquiries of many ages; the ideas which it embodies are the results of long-continued investigations, and the residue of many successive phases of opinion.

Animal
and vital
spirits.

In the natural hierarchy of the sciences, physiology follows after chemistry, which in turn follows physics, molar and molecular; and in a natural development, as indeed is evident from what we have just seen, the study of the two latter should precede that of the former. At a very early age, however, the exigencies of life brought the study of man, and so of physiology, to the front before its time; hence the history of physiology consists to a large extent, especially in its opening chapters, of premature vain attempts to solve physical and chemical problems before the advent of adequate physical or chemical knowledge. But no ignorance of these matters could hide from the observant mind, even in quite early times, two salient points which appear also in the analysis just given, namely, that, while some of the phenomena of living beings seem due to powers wholly unknown in things which are not living, other phenomena, though at first sight special to living beings, appear to be in reality the peculiar outcome of processes taking place as well in things not alive. It was further early seen that, while the former are much more conspicuous, and make up a greater part of the life of the individual in those living beings which are called animals, especially in man, and in animals more closely resembling man, than in those which are called plants, the latter are common to both divisions of living things. Both sets of phenomena, however, were at first regarded as the products of certain special agencies; both were spoken of as the work of certain spirits; and the distinction between the two was formulated by speaking of the spirits as being in the former case *animal* and in the latter *vital*.

From the very outset even the casual observer could not fail to be struck with the fact that many of the processes of living beings appear to be the results of the various contrivances or machines of which a living body is largely built up. This indeed was evident even before the distinction between animal and vital spirits was recognized; and, when that differentiation was accepted, it was seen that the part played by these machines and contrivances in determining the actions of living beings was much more conspicuous in the domain of vital than of animal spirits. As inquiry was pushed forward the prominence and importance of this machinery became greater and greater, more especially since the phenomena supposed to be due to the agency of vital spirits proved more open to direct observation and experiment than those attributed to the animal spirits. It was found that the most fruitful path of investigation lay in the direction of studying the structure and independent action of the several constituent machines of the body, and of unravelling their mutual relations.

Organs
and func-
tions.

These machines received the names of organs, the work or action of an organ being at a later period spoken of as its function. And, when it became clear that many of the problems concerned with what was supposed to be the work of the vital spirits could be solved by the proper appreciation of the functions of certain organs, it was inferred that the more difficult problems belonging to the animal spirits could be solved in the same way. Still later on it was found that the conception of organs and functions was not only quite separable from, but indeed antagonistic to, the hypothesis of the entities called spirits.

In this way the first great phase, as it may be called, of the science of physiology was evolved,—a phase which lasted till quite recent times. Under this conception every living being, plant or animal, was regarded as a complex of organs, each with its respective function, as an engine built up of a number of intricately contrived machines, each performing its specific work. The whole animal body was parcelled out into organs, each of which was supposed to have its appropriate function; and the

efforts of investigators were directed, on the one hand, to a careful examination of the structural features of an organ with the view of determining by deduction what its function must be, and, on the other hand, to confirming or correcting by observation and experiment the conclusions thus reached by the anatomical method. And the fruitfulness of this line of inquiry proved so great that the ideas directing it became absolutely dominant. In many cases the problem to be worked out was in reality a purely mechanical one. This was notably so in the great question of the circulation so brilliantly solved by Harvey. Putting aside for a while the inquiry as to the origin of the force with which the walls of the heart press on the blood contained in its cavities, accepting the fact that the blood is thus pressed at each beat of the heart, all the other truths of the circulation which Harvey demonstrated are simply the outcome of certain mechanical conditions, such as the position and arrangement of the valves, the connexion of various patent tubes, and the like. And many other problems—as, for instance, those connected with respiration—proved to be similarly capable of solution by the application of ordinary mechanical principles to anatomical facts.

So fruitful, and consequently so adequate, seemed this conception of living beings as built up of contrivances or organs, in contrast with the lifeless world in whose monotonous masses no such structural disposition could be recognized, that the word “organic” came into use as a term distinctive of living things. The phrase was especially adopted by the chemists, who for a long time classified their material into “organic” substances, *i.e.*, substances found only in living beings, and into inorganic substances, that is, substances occurring in lifeless bodies as well. Indeed, this nomenclature has not even yet been wholly abandoned. Triumphant, however, as was this mode of inquiry in these and similar instances, there remained in every investigation an unsolvable residue, like the question of the origin of the force exerted by the heart referred to above in speaking of Harvey’s work; and in many other instances the questions which could not be solved on mechanical principles formed a great part of the whole problem. Thus in the case of the liver careful dissection showed that minute tubes starting from all parts of the liver joined into one large canal, which opened into the small intestine, and observation and experiment taught that these tubes during life conveyed from the liver to the intestine a peculiar fluid called bile, which appeared on the one hand to originate in the liver, and on the other to be used up for some purposes in the intestine. But here the mere mechanical flow of the bile along the gall-ducts, instead of being of primary, was merely of secondary importance, and the problem of how the bile was generated and made its way into the small beginnings of the ducts was the greater part of the whole matter. This latter problem was left unsolved, and indeed for a while unattempted. Nevertheless the success in other directions attending the conception of organs and functions encouraged physiologists to speak of the liver as an organ whose function was to secrete bile, and further, led them to ignore to a large extent the great unsolved portion of the problem, and to regard the mere enunciation of the function as the chief end of physiological inquiry.

Moreover, whenever attempts were made to unravel these obscurer problems, the efforts of investigators were mainly confined to a fuller and more complete elucidation of the supposed function of an organ, and the method of inquiry adopted was in most cases one which regarded the finer elements of the part studied as minute organs making up the whole gross organ, and which sought to explain the functions of these smaller organs on the same mechanical

principles which had proved so successful in the case of the whole organ. When the improvements in the microscope opened up a new world to the anatomist, and a wholly fresh mechanical analysis of the structure of living bodies became possible, great hopes were entertained that the old method applied to the new facts would soon solve the riddles of life by showing how the mysterious operations of the living substances out of which the grosser organs were built were the outcome of structural arrangements which had hitherto remained invisible, were in fact the functions of minute component organs. A vision of a grand simplicity of organic nature dawned upon the minds of physiologists. It seemed possible to conceive of all living beings as composed of minute organic units, of units whose different actions resulted from their different structural characters, whose functions were explicable by, and could be deduced from, their anatomical features, such units being built up into a number of gross organs, the functions of each of which could in turn be explained by the direction which its mechanical build gave to the efforts of its constituent units. Such a view seemed to have touched the goal, when, in the first half of this century, the so-called "cell-theory" was enunciated as a physiological generalization.

Long before, in the previous century, the genius of Caspar Wolff had led him to maintain that the bodies of living beings may be regarded as composed of minute constituent units, which, being in early life all alike and put together as an unformed mass, gradually differentiate and are ultimately arranged into the tissues and organs of the adult being. But, though Wolff was not unaware of the physiological bearing of his conception, his mind was chiefly bent towards morphological views, and his cell-theory is essentially a morphological one. The cell-theory, however, which became famous in the third decade of the present century, and to which the twin names of Schwann and Schleiden will always be attached, was essentially a physiological one. The chief interest which these authors felt in the ideas that they put forth centred in the conviction that the properties of the cell as they described it were the mechanical outcome of its build; and for a time it seemed possible that all physiological phenomena could be deduced from the functions of cells, the anatomical characters of the various kinds of cells determining in turn their special functions. In the cell-theory the conception of organs and functions reached its zenith; but thenceforward its fall, which had been long prepared, was swift and great. Two movements especially hurried on its decline.

It had long been a reproach to physiologists that, while to most organs of the body an appropriate function had been assigned, in respect to certain even conspicuous organs no special use or definite work could be proved to exist. Of these apparently functionless organs the most notorious instance was that of the spleen, a large and important body, whose structure, though intricate, gave no sign of what its labours were, and whose apparent uselessness was a stumbling-block to the theological speculations of Paley. While in the case of other organs a definite function could be readily enunciated in a few words, and their existence therefore easily accounted for, the spleen remained an opprobrium, existing, as it appeared to do, without purpose, and therefore without cause.

The progress of discovery during the present century, by a cruel blow, instead of pointing out the missing use of the spleen, rudely shook the confidence with which the physiologists concluded that they had solved the riddle of an organ when they had allotted to it a special function. From very old times it had been settled that the function of the liver was to secrete bile; and the only problems

left for inquiry as touching the liver seemed to be those which should show how the minute structure of the organ was adapted for carrying on this work. About the middle of this century, however, the genius of Claude Bernard led him to the discovery that the secretion of bile was by no means the chief labour of the liver. He showed that this great viscus had other work to do than that of secreting bile, had another "function" to perform, but a function which seemed to have no reference whatever to the mechanical arrangements of the organ, which could never have been deduced from any inspection however complete of its structure, even of its most hidden and minute features, and which therefore could not be called a function in the old and proper sense of that word. By a remarkable series of experiments, which might have been carried out by one knowing absolutely nothing of the structural arrangements of the liver beyond the fact that blood flowed to it along the portal vein, and from it along the hepatic vein, he proved that the liver, in addition to the task of secreting bile, was during life engaged in carrying on a chemical transformation by means of which it was able to manufacture and store up in its substance a peculiar kind of starch, to which the name of *glycogen* was given. Bernard himself spoke of this as the glycogenic function of the liver, but he used the word "function" in a broad indefinite sense, simply as work done, and not in the older narrower meaning as work done by an organ structurally adapted to carry on a work which was the inevitable outcome of the form and internal build of the organ. In this glycogenic function organization, save only the arrangements by means of which the blood flows on from the portal to the hepatic channels in close proximity to the minute units of the liver-substance, the so-called hepatic cells, appeared to play no part whatever; it was not a function, and in reference to it the liver was not an organ, in the old senses of the words. This discovery of Bernard's threw a great flash of light into the darkness hitherto hiding the many ties which bound together distant and mechanically isolated parts of the animal body. Obviously the liver made this glycogen, not for itself, but for other parts of the body; it laboured to produce, but they made use of, the precious material, which thus became a bond of union between the two.

The glycogenic labours of the simple hepatic substance carried out independently of all intricate structural arrangements, and existing in addition to the hepatic function of secreting bile, being thus revealed, men began to ask themselves the question, May not something like this be true of other organs to which we have allotted a function and thereupon rested content? And further, in the cases where we have striven in hope, and yet in vain, to complete the interpretation of the function of an organ, by finding in the minute microscopic details of its structure the mechanical arrangements which determine its work, may we not have followed throughout a false lead, and sought for organization where organization in our sense of the word does not exist? The answer to this question, and that an affirmative one, was hastened by the collapse of the cell-theory on its physiological side, very soon after it had been distinctly formulated.

The "cell," according to the views of those who first propounded the cell-theory, consisted essentially of an envelope or "cell-membrane," of a substance or substances contained within the cell-membrane, hence called cell-contents, and of a central body or kernel called the "nucleus," differing in nature from the rest of the cell-contents. And, when facts were rapidly accumulated, all tending to prove that the several parts of the animal or vegetable body, diverse as they were in appearance and structure, were all built up of cells more or less modified,

the hope arose that the functions of the cell might be deduced from the mutual relations of cell-membrane, cell-contents, and nucleus, and that the functions of an organ might be deduced from the modified functions of the constituent modified cells. Continued investigation, however, proved destructive of this physiological cell-theory. It soon became evident that the possession of an investing envelope or cell-membrane was no essential feature of a cell, and that even the central kernel or nucleus might at times be absent. It was seen in fact that the anatomical unit need have no visible parts at all, but might be simply a minute mass, limited in various ways, of the material spoken of as cell-contents. Under the cell-theory, the cell was supposed to be the first step in organization, the step by which a quantity of formless unorganized plasm became an organized unit; this plasm was further supposed still to form the chief part of the cell-contents, and soon became recognized under the name of protoplasm. Hence the destructive anatomical researches which deprived the cell of its cell-membrane, and even of its nucleus, left nothing except a mass of protoplasm to constitute an anatomical unit. For such a unit the word "cell" was a misnomer, since all the ideas of organization denoted by the word had thus vanished; nevertheless it was retained with the new meaning, and up to the present time the definition of a cell is that of a limited mass of protoplasm, generally but not always containing a modified kernel or nucleus.

Proto-
plasm.

Proto-
plasmic
theory.

With this anatomical change of front the physiological cell-theory was utterly destroyed. The cell was no longer a unit of organization; it was merely a limited mass of protoplasm, in which, beyond the presence of a nucleus, there was no visible distinction of parts. It was no longer possible to refer the physiological phenomena of the cell to its organization; it became evident that the work done by a "cell" was the result not of its form and cellular structure but simply of the nature and properties of the apparently structureless protoplasm which formed its body. A new idea pressed itself on men's minds, that organization was a concomitant and result of vital action, not its condition and cause; as Huxley in one of his earliest writings put it, "They [cells] are no more the producers of the vital phenomena than the shells scattered in orderly lines along the sea-beach are the instruments by which the gravitative force of the moon acts upon the ocean. Like these, the cells mark only where the vital tides have been, and how they have acted."¹ Hence arose the second of the two movements mentioned above, that which may be called the "protoplasmic" movement, a movement which, throwing overboard altogether all conceptions of life as the outcome of organization, as the mechanical result of structural conditions, attempts to put physiology on the same footing as physics and chemistry, and regards all vital phenomena as the complex products of certain fundamental properties exhibited by matter, which, either from its intrinsic nature or from its existing in peculiar conditions, is known as living matter,—mechanical contrivances in the form of organs serving only to modify in special ways the results of the exercise of these fundamental activities and in no sense determining their initial development.

Tissues.

Long before the cell-theory had reduced to an absurdity the "organic" conception of physiology, the insight of the brilliant Bichat, so early lost to science, had led him to prepare the way for modern views by developing his doctrine of "tissues." That doctrine regarded the body as made up of a number of different kinds of living material, each kind of material having certain innate qualities proper to itself

as well as certain structural features, and the several kinds of material being variously arranged in the body. Each of these body-components was spoken of as a tissue, muscular tissue, nervous tissue, and the like; and the varied actions of the body were regarded as the result of the activities of the several tissues modified and directed by the circumstance that the tissues were to a great extent arranged in mechanical contrivances or organs which largely determined the character and scope of their actions.

The imperfection of microscopic methods in Bichat's time, and, we may perhaps add, his early death, prevented him from carrying out an adequate analysis of the qualities or properties of the tissues themselves. During the middle portion of this century, however, histological investigation, i.e., inquiry into the minute structure of the tissues, made enormous progress, and laid the basis for a physiological analysis of the properties of tissues. In a short time it became possible to lay down the generalization that all the several tissues arise, as far as structure is concerned, by a differentiation of a simple primitive living matter, and that the respective properties of each tissue are nothing more than certain of the fundamental properties of the primordial substance thrown into prominence by a division of labour running to a certain extent parallel to the differentiation of structure. Developed in a fuller manner, this modern doctrine may be expounded somewhat as follows.

In its simplest form, a living being, as illustrated by some of the forms often spoken of as amœbæ, consists of a mass of substance in which there is no obvious distinction of parts. In the body of such a creature even the highest available powers of the microscope reveal nothing more than a fairly uniform network of material, a network sometimes compressed, with narrow meshes, sometimes more open, with wider meshes, the intervals of the meshwork being filled, now with a fluid, now with a more solid substance or with a finer and more delicate network, and minute particles or granules of variable size being sometimes lodged in the open meshes, sometimes deposited in the strands of the network. Sometimes, however, the network is so close, or the meshes filled up with material so identical in refractive power with the bars or films of the network, and at the same time so free from granules, that the whole substance appears absolutely homogeneous, glassy or hyaline. Analysis with various staining and other reagents leads to the conclusion that the substance of the network is of a different character from the substance filling up the meshes. Similar analysis shows that at times the bars or films of the network are not homogeneous, but composed of different kinds of stuff; yet even in these cases it is difficult if not impossible to recognize any definite relation of the components to each other such as might deserve the name of structure; and certainly in what may be taken as the more typical instance, where the network seems homogeneous, no microscopic search is able to reveal to us a distinct structural arrangement in its substance. In all probability optical analysis, with all its aids, has here nearly reached its limits; and, though not wholly justified, we may perhaps claim the right to conclude that the network in such case is made up of a substance in which no distinction of parts will ever be visible, though it may vary in places or at times in what may be spoken of as molecular construction, and may carry, lodged in its own substance, a variety of matters foreign to its real self. This remarkable network is often spoken of as consisting of protoplasm, and, though that word has come to be used in several different meanings, we may for the present retain the term. The body of an amœba, then, or of a similar organism consists of a network or framework which we may speak of as protoplasm, filled up with other matters. In most cases it is true that in

¹ "The Cell-Theory," in *Brit. and For. Med. Chir. Rev.*, vol. xii. (1858) p. 314.

the midst of this protoplasmic body there is seen a peculiar body of a somewhat different and yet allied nature, the so-called nucleus; but this we have reason to think is specially concerned with processes of division or reproduction, and may be absent, for a time at all events, without any injury to the general properties of the protoplasmic body.

Now such a body, such a mass of simple protoplasm, homogeneous save for the admixtures spoken of above, is a living body, and all the phenomena which we sketched out at the very beginning of this article as characteristic of the living being may be recognized in it. There is the same continued chemical transformation, the same rise and fall in chemical dignity, the same rise of the dead food into the more complex living substance, the same fall of the living substance into simpler waste-products. There is the same power of active movement, a movement of one part of the body upon another giving rise to a change of form, and a series of changes of form resulting eventually in a change of place. In what may be called the condition of rest the body assumes a more or less spherical shape. By the active transference of part of the mass in this or that direction the sphere flattens itself into a disk, or takes on the shape of a pear, or of a rounded triangle, or assumes a wholly irregular, often star-shaped or branched form. Each of these transformations is simply a rearrangement of the mass, without change of bulk. When a bulging of one part of the body takes place there is an equivalent retraction of some other part or parts; and it not unfrequently happens that one part of the body is repeatedly thrust forward, bulging succeeding bulging, and each bulging accompanied by a corresponding retraction of the opposite side, so that, by a series of movements, the whole body is shifted along the line of the protuberances. The tiny mass of simple living matter moves onward, and that with some rapidity, by what appears to be a repeated flux of its semi-liquid substance.

The internal changes leading to these movements may begin, and the movements themselves be executed, by any part of the uniform body; and they may take place without any obvious cause. So far from being always the mere passive results of the action of extrinsic forces, they may occur spontaneously, that is, without the coincidence of any recognizable disturbance whatever in the external conditions to which the body is exposed. They appear to be analogous to what in higher animals we speak of as acts of volition. They may, however, be provoked by changes in the external conditions. A quiescent amoeba may be excited to activity by the touch of some strange body, or by some other event,—by what in the ordinary language of physiology is spoken of as a stimulus. The protoplasmic mass is not only mobile but sensitive. When a stimulus is applied to one part of the surface a movement may commence in another and quite distant part of the body; that is to say, molecular disturbances appear to be propagated along its substance without visible change, after the fashion of the nervous impulses we spoke of in the beginning of this article. The uniform protoplasmic mass of the amoeba exhibits the rudiments of those attributes or powers which in the initial sketch we described as being the fundamental characteristics of the muscular and nervous structures of the higher animals.

These facts, and other considerations which might be brought forward, lead to the tentative conception of protoplasm as being a substance (if we may use that word in a somewhat loose sense) not only unstable in nature but subject to incessant change, existing indeed as the expression of incessant molecular, that is, chemical and physical change, very much as a fountain is the expression of an incessant replacement of water. We may picture to

ourselves this total change which we denote by the term "metabolism" as consisting on the one hand of a downward series of changes (*katabolic* changes), a stair of many steps, in which more complex bodies are broken down with the setting free of energy into simpler and simpler waste bodies, and on the other hand of an upward series of changes (*anabolic* changes), also a stair of many steps, by which the dead food, of varying simplicity or complexity, is, with the further assumption of energy, built up into more and more complex bodies. The summit of this double stair we call "protoplasm." Whether we have a right to speak of it as a single body, in the chemical sense of that word, or as a mixture in some way of several bodies, whether we should regard it as the very summit of the double stair, or as embracing as well the topmost steps on either side, we cannot at present tell. Even if there be a single substance forming the summit, its existence is absolutely temporary: at one instant it is made, at the next it is unmade. Matter which is passing through the phase of life rolls up the ascending steps to the top, and forthwith rolls down on the other side. But to this point we shall return later on. Further, the dead food, itself fairly but far from wholly stable in character, becomes more and more unstable as it rises into the more complex living material. It becomes more and more explosive, and when it reaches the summit its equilibrium is overthrown and it actually explodes. The whole downward stair of events seems in fact to be a series of explosions, by means of which the energy latent in the dead food and augmented by the touches through which the dead food becomes living protoplasm, is set free. Some of this freed energy is used up again within the material itself, in order to carry on this same vivification of dead food; the rest leaves the body as heat or motion. Sometimes the explosions are, so to speak, scattered, going off as it were irregularly throughout the material, like a quantity of gunpowder sprinkled over a surface, giving rise to innumerable minute puffs, but producing no massive visible effects. Sometimes they take place in unison, many occurring together, or in such rapid sequence that a summation of their effects is possible, as in gunpowder rammed into a charge, and we are then able to recognize their result as visible movement, or as appreciable rise of temperature.

These various phenomena of protoplasm may be conveniently spoken of under the designation of so many properties, or attributes, or powers of protoplasm, it being understood that these words are used in a general and not in any definite scholastic sense. Thus we may speak of protoplasm as having the power of *assimilation*, i.e., of building up the dead food into its living self; of movement, or of *contractility* as it is called, i.e., of changing its form through internal explosive changes; and of *irritability* or *sensitiveness*, i.e., of responding to external changes, by less massive internal explosions which, spreading through its mass, are not in themselves recognizable through visible changes, though they may initiate the larger visible changes of movement.

These and other fundamental characters, all associated with the double upward and downward series of chemical changes, of constructive and destructive metabolism, are present in protoplasm wherever found; but a very brief survey soon teaches us that specimens of protoplasm existing in different beings or in different parts of the same being differ widely in the relative prominence of one or another of these fundamental characters. On the one hand, in one specimen of protoplasm the energy which is set free by the series of explosions constituting the downward changes of destructive metabolism may be so directed as to leave the mass almost wholly in the form of heat, thus producing very little visible massive change of form. Such a protoplasm consequently, however irritable and

Constructive and destructive metabolism.

Properties of protoplasm.

explosive, exhibits little power of contractility or movement. In another specimen, on the other hand, a very large portion of the energy similarly set free may be spent in producing visible changes of form, the protoplasm in this instance being exquisitely mobile. Such differences must be due to different internal arrangements of the protoplasm, though, since no vision, however well assisted, can detect these arrangements, they must be of a molecular nature rather than of that grosser kind which we generally speak of as structural. It is true that, as the differences in properties become more and more prominent, as the protoplasm becomes more and more specialized, features which we can recognize as structural intervene; but even these appear to be subsidiary, to accompany and to be the result of the differences in property, or to be concerned in giving special directions to the activities developed, and not to be the real cause of the differences in action. We are thus led to the conception of protoplasm as existing in various differentiated conditions while still retaining its general protoplasmic nature, a difference of constitution making itself felt in the different character of the work done, in a variation of the results of the protoplasmic life. We have a division of physiological labour going hand in hand with a differentiation of material, accompanied ultimately by morphological results which may fairly be spoken of as constituting a differentiation of structure.

Some of the simpler and earlier features of such a division and differentiation may be brought out by comparing with the life of such a being as the amoeba that of a more complex and yet simple organism as the hydra or freshwater polyp. Leaving out certain details of structure, which need not concern us now, we may say that the hydra consists of a large number of units or cells firmly attached to each other, each cell being composed of protoplasm, and in its broad features resembling an amoeba. The polyp is in fact a group or crowd of amoeba-like cells so associated together that, not only may the material of each cell, within limits, be interchanged with that of neighbouring cells, but also the dynamic events taking place in one cell, and leading to exhibitions of energy, may be similarly communicated to neighbouring cells, also within limits. These cells are arranged in a particular way to form the walls of a tube, of which the body of the hydra practically consists. They form two layers in apposition, one an internal layer called the *endoderm*, lining the tube, the other an external layer called the *ectoderm*, forming the outside of the tube. And, putting aside minor details, the differences in structure and function observable in the organism are confined to differences between the ectoderm on the one hand, all the constituent cells of which are practically alike, and the endoderm on the other, all the cells of which are in turn similarly alike. The protoplasm of the ectoderm cells is so constituted as to exhibit in a marked degree the phenomena of which we spoke above as irritability and contractility, whereas in the endoderm these phenomena are in abeyance, those of assimilation being prominent. The movements of the hydra are chiefly brought about by changes of form of the ectoderm cells, especially of tail-like processes of these cells, which, arranged as a longitudinal wrapping of the tubular body, draw it together when they shorten, and lengthen it out when they elongate, and it is by the alternate lengthening and shortening of its body, and of the several parts of its body, that the hydra changes its form and moves from place to place. Inaugurating these changes of form, the products of contractility, are the more hidden changes of irritability; these also are especially developed in the ectoderm cells, and travel readily from cell to cell, so that a disturbance originating in one cell, either from some extrinsic cause, such as contact with a

foreign body, or from intrinsic events, may sweep from cell to cell over the surface of the whole body. The animal feels as well as moves by means of its ectoderm cells. In the endoderm cells the above phenomena, though not wholly absent, are far less striking, for these cells are almost wholly taken up in the chemical work of digesting and assimilating the food received into the cavity, the lining of which they form.

Thus the total labour of the organism is divided between these two membranes. The endoderm cells receive food, transmute it, and prepare it in such a way that it only needs a few final touches to become living material, these same cells getting rid at the same time of useless ingredients and waste matter. Of the food thus prepared the endoderm cells, however, themselves use but little; the waste of substance involved in the explosions which carry out movement and feeling is reduced in them to a minimum; they are able to pass on the greater part of the elaborated nourishment to their brethren the ectoderm cells. And these, thus amply supplied with material which it needs but little expenditure of energy on their part to convert into their living selves, thus relieved of the greater part of nutritive labour, are able to devote nearly the whole of their energies to movement and to feeling.

Microscopic examination further shows that these two kinds of cells differ from each other to some extent in visible characters; and, though, as we have seen, the differences in activity appear to be dependent on differences in invisible molecular arrangement rather than on gross visible differences such as may be called structural, still the invisible differences involve or entail, or are accompanied by, visible differences, and such differences as can be recognized between endoderm and ectoderm, even with our present knowledge, may be correlated to differences in their work; future inquiry will probably render the correlation still more distinct.

The ectoderm cells together constitute what we have spoken of above as a tissue, whose function in the modern sense of the word is movement and feeling, and the endoderm cells constitute a second tissue, whose function is assimilation; and the phenomena of the whole being result from the concurrent working of these two functions. Of organs, in the old sense of the word, of mechanical contrivances, there is hardly a trace.¹ The performances of the being are, it is true, conditioned by its being moulded in the form of a long tubular sac with a crown of like tubular arms, but beyond this the explanation of every act of the hydra's life is first to be sought in the characters of the endoderm and ectoderm. The physiology of the hydra is, for the most part, a series of problems, dealing on the one hand with the intimate nature of the ectodermic protoplasm and the changes in that protoplasm which give rise to movement and feeling, as well as with the laws whereby those changes are so regulated that movement and feeling come and go as the needs of the organism may require, and on the other hand with the intimate nature of the endodermic protoplasm and the changes in that protoplasm whereby the dead food is, also according to the needs of the economy, transformed into living substance. Whereas the older physiology dealt almost exclusively with mechanical problems, the physiology of to-day is chiefly busied with what may be called molecular problems.

The physiology of the higher animals, including man, is merely a development of the simpler physiology of the hydra, which has been rendered more complex by a greater division of physiological labour, entailing greater differen-

¹ The existence of certain minute mechanisms called urticating organs lodged in the ectoderm cells does not affect the present argument.

tiation of structure, and been varied by the intercalation of numerous mechanical contrivances.

Differ-
entia-
tion of
ecto-
derm.

In the hydra each ectoderm cell—for, broadly speaking, they are all alike—serves three chief purposes of the body. (1) It is sensitive, that is, it is thrown into peculiar molecular agitations, with expenditure of energy, when acted upon by external agents. In man and the higher animals certain cells of the original ectoderm of the embryo are differentiated from their fellows (which, losing to a large extent this sensitiveness, remain as a mechanical covering to the body) by a more exquisite development of this power of reaction, and moreover are differentiated from each other in their relative sensitiveness to different agents, so that one set of cells becomes peculiarly susceptible to light, another set to pressure, and the like. Thus the uniform ectoderm of the hydra, uniformly susceptible to all agencies, is replaced by a series of special groups of cells forming the basis of sensory organs, each group being specially sensitive to one agent, and having the nature of its constituent cells correspondingly modified. (2) In each ectoderm cell of the hydra the agitations primarily induced by the exciting agent become so modified by changes taking place in the cell that the outcome is not always the same. According to processes taking place in the cell, movement of one kind or another, or no movement at all, may result, and such movement as results may take place immediately or at some other time; it may be at a time so distant that the connexion between the exciting disturbance is lost, and the movement appears to be spontaneous. In man and the higher animals these more complex “neural” processes are carried on, not by the simple sensory cells which receive the primary impression, but by a group of cells set apart for the purpose. These cells constitute a central nervous system, in which a still further division of labour and differentiation of structure takes place, the simple neurotic processes of the hydra, with its dim volition and limited scope of action, being developed in a complex manner into processes which range from simple elaboration of the initial additional agitation of the sensory cell into what we speak of as intelligence and thought. (3) Each ectoderm cell, by its tail-like prolongation, or by its whole body, contributes to the movement of the animal while still carrying on the two other actions just described. In man and the higher animals the material of the sensory cell and of the central nervous cells is too precious to be wasted in movements; these accordingly are carried out by groups of cells constituting the muscular tissue, in which both the sensitiveness and the higher neurotic processes of the primitive cell are held in abeyance; indeed, the latter have almost disappeared in order that the energy of the protoplasm may be more completely directed to producing those changes of form which determine the movements of the animal.

Further, the separation in space of these three groups of cells or tissues necessitates the introduction of elements whereby the agitations set up in the sensory cell should be communicated to the central nervous cells, where these agitations are further elaborated, as well as of elements whereby the muscular tissue may receive vibrations from the central nervous cells, so that the movements of the body may be determined by these. Hence strands of irritable protoplasm whose energy is not spent in movement, but wholly given up to the rapid and easy transmission of molecular vibrations, unite, as sensory nerves, the sensory cells with the central nervous cells, and, as motor nerves, these with the muscles.

Lastly, for the adequate carrying out of complex movements, the contractile cells, elongated into specially constructed fibres and constituting the muscles, are arranged, with inert tissues such as bones, cartilages, tendons, and

the like (tissues of mechanical virtues, manufactured by an active protoplasm, but themselves passive, no longer active), into various mechanical contrivances. Similarly the sensory cells, as notably those of the eye and the ear, set apart to be acted upon by special agents, are provided with special mechanisms in order that the agent may act with more complete precision. Thus the sensory cells constituting the retina of the eye, in which alone sensory, visual impulses are generated, are provided with an intricate dioptric mechanism, formed partly of inert tissues such as the lens, partly of peculiarly arranged muscular and nervous elements.

In this way the simple ectoderm of the hydra is replaced by a complicated system composed of organs, some of them of extremest intricacy. But the whole system may be reduced to two sets of factors. On the one hand there are organs in the old sense of the word, that is, mechanical arrangements, some connected with the muscles and others connected with the sensory cells, organs whose functions have for the most part to be interpreted on mechanical principles, since their most important factors, putting aside intervening muscular and nervous elements, are the inert products of protoplasm doing simple mechanical work. On the other hand there are organs in the later sense of the word, namely, sensory cells differentiated to be sensitive to special influences, central nervous cells differentiated to carry on the inner nervous work, muscles differentiated to contract, and nerves differentiated to bind together these three other factors. The work of these latter organs is dependent on the nature of their protoplasm; mechanical arrangements play but little part in them; and the results of their activity can in no way be explained on simple mechanical principles.

Corresponding with this differentiation of the ectoderm cells runs a somewhat similar differentiation of the endoderm cells. In the hydra each endoderm cell appears to receive some of the food bodily into itself and there to elaborate it into what may be spoken of as prepared nutritive material. Some of this material the cell retains within itself in order to renew its own protoplasm; the rest oozes out to the ectoderm cells, the replenishment of whose protoplasm is thereby effected with a saving of labour. In the higher animals the preparation of food is far more complicated. The endodermic sheet of the alimentary canal is folded and arranged into organs called glands, with the mechanical advantage that a large amount of surface is secured within a small bulk; and the constituent endodermic cells of their glands pour out, or secrete, as is said, divers fluids into the cavity of the canal, so that much preliminary preparation of digestion of the food takes place before the food really enters the body. Further, these secreting glandular cells are so differentiated as to pour out special juices acting on special constituents of a meal, and the food subjected in turn to the action of these several juices becomes thoroughly prepared for reception into the body. This reception is carried out by other endoderm cells, which in receiving the digested food probably act upon it so as still further to heighten its nutritive value; and the absorbed food, before it is presented to the muscular and nervous tissues, for whose use it is largely, though of course not exclusively, intended, is subjected to the action of other cells, such as those forming the lymphatic glands and the liver, in order that it may be still further elaborated, still further prepared for the final conversion into living protoplasm.

As in the case of the tissues and organs of ectodermic origin, so also here, the wide separation in space of the masses of differentiated cells constituting tissues necessitates the introduction of mechanical contrivances for the carriage of material from place to place. In the simple

Differ-
entia-
tion of
endo-
derm.

Vascular system. minute hydra the nutritive material can permeate the whole body by simply oozing from cell to cell. In the higher animal a hydraulic system for the distribution of nutritive material is introduced. A fluid is distributed in a ceaseless flow all over the body by a mechanical arrangement, consisting of a pump with branching tubes, worked on mechanical principles, and capable of being imitated artificially, save that the power which drives the machine is the energy set free by living muscle. As this circulating fluid or blood rushes past the endoderm cells which have gorged themselves from the rich contents of the alimentary canal, it receives from them some of the material which they have absorbed and elaborated, and carries this nutritive supply to muscles, nerves, and all parts of the body. Similarly it carries away from muscles, nerves, and other tissues the waste-products of their activity, those broken fragments of simpler stuffs into which, as we have seen, the complex protoplasm, wherever it exists, is for ever splitting up, and bears them back to differentiated endoderm and other cells, whose work has become, so to speak, inverted, since their activity is directed to casting things out of the body, instead of receiving things into the body. And lastly, by a special arrangement, by a peculiar property of those red corpuscles which make blood red, this circulating material at one and the same time carries to each corner of the body, not only the nutritive material required for building up protoplasm, but also the oxygen by which the constructed protoplasm may suffer oxidation, and in being oxidized set free that energy the manifestation of which is the token of life. Blood is in fact the medium on which all the various parts of the body live. Just as an amoeba finds in the water which is its home both the food with which it builds itself up and the oxygen with which it breaks itself down, and returns to the water the waste-products of its continued disintegration, so each islet of the living substance of the higher animal, be it muscle or nerve or gland, draws its food and its oxygen from the red blood-stream sweeping past it, finding therein all its needs, and sheds into the same stream the particles into which it is continually breaking up, and for which it has no longer any use. Hence the blood becomes, as it were, a chemical epitome of the body: from it each tissue takes something away; to it each tissue gives something back. As it sweeps by each tissue, losing and gaining, it makes the whole body common, and when working aright brings it about that each tissue is never in lack of the things which it wants, never choked up with the things with which it has done.

This vascular system, consisting of a force-pump and branching tubes, constitutes, as we have said, a mechanical arrangement worked on mechanical principles. Nevertheless occult protoplasmic processes intervene as factors in its total work. Not only is the force-pump itself a living muscular organ, not only are the walls of the tubes muscular in nature, so that the mere mechanical working of the system is modified by changes not of mechanical origin taking place in them, but the living material which lines the tubing throughout, especially in the minuter channels, finds work to do, also not of a mechanical nature. The gross phenomena of the flow of blood through the capillary channels may (see **VASCULAR SYSTEM**) be interpreted on simple hydraulic principles; but no appeal to the ordinary physical laws of dead material will explain the phenomena of the interchange between the blood on the inside of a capillary wall and the tissue-elements on the outside. In every tissue, be it gland, muscle, or nerve, the blood, so far from being actually in contact with the active protoplasmic units of the tissue, is separated by the protoplasmic film of the capillary wall, and by a space or spaces, greater or smaller, filled with the fluid called lymph

and lined to a greater or less extent with protoplasmic cells, which lining, often at least, parts the tissue-units from the lymph. Hence the tissue lives upon the lymph, while the lymph is replenished from the blood; and the interchange between the tissue-unit and the blood is determined, not only by the direct action of the tissue-unit on the lymph, but also by the relations of the lymph to the blood, as regulated by the capillary wall and the cellular lining of the lymph-spaces. We may speak of the interchange as broadly one of diffusion or osmosis through filmy membranes; but diffusion is not the lord in the matter: it is rather a humble servant directed hither and thither by occult molecular processes in the protoplasmic structures concerned.

The foregoing rough analysis leads to a conception of the physiology of the animal body which may be expressed somewhat as follows. The body is composed of different kinds of matter; each kind of matter, arranged in units more or less discrete, constitutes a tissue; and the several tissues, though having a common likeness in token of their origin from a common primordial protoplasm, have dissimilar molecular constitutions, entailing dissimilar modes of activity. Nor is each tissue homogeneous, for two parts of the body, though so far alike as to be both examples of the same general tissue, may be different in molecular constitution, more or less distinctly expressed by microscopic differences of structure, and correspondingly different in action. Thus a liver-cell and a kidney-cell, though both examples of glandular tissue, are quite distinct; so also several varieties of muscular tissue exist; and in the dominant nervous tissue we have not only a broad distinction between nerve-fibres and nerve-cells, but the several groups of nerve-cells which are built up into the brain and spinal cord, and indeed probably the single nerve-cells of these, though all possessing the general characters, both in structure and function, of nervous protoplasm, differ most widely from each other. These several tissues of diverse constitution and activity, ranging as regards the rapidity of the molecular changes taking place in them from the irritable, unstable, swiftly-changing nerve-cell to the stable, slowly-changing, almost lifeless tendon or bone, are disposed in the body in various mechanical arrangements constituting organs or machines, whereby the activities of the constituent tissue-elements are brought to bear in special directions. These organs range from those in which the mechanical provisions are dominant, the special activity of the tissue-elements themselves being in the background, and supplying only an obscure or even unimportant factor, as in the organs of respiration, to those in which the mechanical provisions are insignificant, as in the central nervous system, where the chief mechanical factor is supplied by the distribution in space of the nerve fibres or cells.

Hence it is obvious that almost every physiological inquiry of any large scope is, or sooner or later becomes, of a mixed nature. On the one hand, investigation has to be directed to the processes taking place in the actual tissue-elements, in the protoplasmic cells and modifications of cells. These are essentially of a molecular, often of a chemical or chemico-physical nature; in the problems thus raised matters of form and structure, other than that of molecular structure, which no microscope can ever reveal, are of secondary moment only, or have no concern in the matter at all. These may be spoken of as the purely physiological or as the molecular problems. On the other hand, the natural results of these tissue-activities are continually being modified by circumstances whose effect can be traced to the mechanical arrangements under which the tissue in question is acting, whence arise problems which have to be settled on simple mechanical principles.

We may take as an illustration the physiology of the

Nature of
physio-
logical
prob-
lems.

kidney. In the old language the function of the kidney is to secrete urine. When we come to inquire into the matter, we find, in the first place, that the secretion of urine—that is, the quantity and quality of the urine escaping from the duct of the kidney in a given period—is partly determined by the quantity of blood passing through the kidney and the circumstances of its passage. Now the quantity of blood reaching the kidney at any one time is dependent partly on the width of the renal arteries, partly on the general pressure of the blood in the arterial system. The width of the renal arteries is in turn dependent on the condition of their muscular walls, whether contracted or relaxed; and this condition is determined by the advent of nervous impulses, the so-called vaso-motor impulses, arising in the central nervous system and passing down to the renal arteries along certain nerves. The emission of these vaso-motor impulses from the central nervous system is further determined, on the one hand by the condition of certain parts of the central nervous system, the so-called vaso-motor centres, and on the other by the passage of certain afferent sensory impulses to those vaso-motor centres from sensory surfaces such as the skin. Similarly the general blood-pressure is dependent on the condition, patent or narrowed, of the small arteries generally, this being likewise governed by the vaso-motor system and on the coincident work done by the heart in driving blood into the great blood-vessels, this work being also governed by the nervous system. Hence in attacking such a problem as to how any particular event, such as the exposure of skin to the cold, influences the flow of blood through the kidney and thus the secretion of urine, the investigator, without staying to inquire into the nature of nervous impulses, or into the nature of changes taking place in vaso-motor centres, &c., directs his attention to determining what impulses are generated under the circumstances, what paths they take, to what extent they are quantitatively modified, how far they and their effects react upon each other, and so on. His inquiry in fact takes on to a large extent the characters of an attempt to unravel an intricate game, in which the counters are nervous impulses, muscular contractions, and elastic reactions, but in which the moves are determined by topographical distribution and mechanical arrangements.

But there are other problems connected with the physiology of the kidney of quite a different nature. The kidney is, broadly speaking, constructed of living protoplasmic cells so arranged that each cell is on one side bathed with blood and lymph, and on the other forms the boundary of a narrow canal, which, joining with other canals, ultimately opens into the urinary bladder. Here the question arises how it is that these protoplasmic cells, having nothing to draw upon but the common blood, which is distributed to other organs and tissues as well, are able to discharge on the other side of them into the canal the fluid urine, which is absolutely distinct from blood, which contains substances wholly unknown in blood, as well as substances which, though occurring in blood, are found there in minute quantities only, and, moreover, are not found to escape from the blood into any other tissues or organs. In attempting to answer this question we come upon an inquiry of quite a different nature from the preceding, an inquiry for the solution of which mechanical suggestions are useless. We have to deal here with the molecular actions of the protoplasmic cell. We must seek for molecular explanations of the questions, why a current sets across the cells from blood-capillary and lymph-space to the hollow canal; why the substances which emerge on the far side are so wholly unlike those which enter in on the near side; why, moreover, the intensity of this current may wax and wane, now flooding the canal with urine, now nearly or quite drying up; why

not only the intensity of the current but also the absolute and relative amount of the chemical substances carried along it are determined by events taking place in the cell itself, being largely independent of both the quantity and quality of the blood which forms the cell's only source of supply. These and other like questions can only be solved by looking with the mind's eye, by penetrating through careful inferences, into those inner changes which we call molecular, and which no optical aid will ever reveal to the physical eye.

These two lines of inquiry, which we may call the mechanical and the molecular, obtain in all parts of physiology, sometimes the one and sometimes the other being dominant. A study of the special articles dealing with the several parts of physiology (see "Nervous System" below, NUTRITION, REPRODUCTION, RESPIRATION, VASCULAR SYSTEM) will perhaps sufficiently show this; but it may be worth while to give a very brief survey of the whole field from this point of view.

The master tissues and organs of the body are the nervous and muscular systems, the latter being, however, merely the instrument to give effect and expression to the motions of the former. All the rest of the body serves simply either in the way of mechanical aids and protection to the several parts of the muscular and nervous systems, or as a complicated machinery to supply these systems with food and oxygen, *i.e.*, with blood, and to keep them cleansed from waste matters throughout all their varied changes. The physiology of the muscular system is fairly simple. The mechanical problems involved have been long ago for the most part worked out, and the molecular problems which touch on the nature of muscular contractions, their dependence on the blood-supply, and their relations to nervous impulses are being rapidly solved. The physiology of the nervous system, on the other hand, is in its infancy. The mechanical side of the inquiry is here represented, inasmuch as the various actions of the system are conditioned by the distribution and topographical arrangement of the constituent fibres and cells; and even these simple problems, as may be seen from the article "Nervous System" below, are as yet largely unworked. The deeper molecular problems, those which deal with the real nature of the processes taking place in cell and fibre, even the simpler of these, such as the one which asks why the neural protoplasm of one cell, or group of cells, seems quiescent until stirred by some foreign impulse, its own vibrations being otherwise retained and lost within its own substance, while the neural protoplasm of another cell is continually, or from time to time, discharging vibrations, as rhythmic molecular pulses, along adjoining fibres,—these, at the present day, can hardly be said to be touched. The physiology of the nervous system is emphatically the physiology of the future.

The rest of the body may, from a broad point of view, be regarded as a complex machinery for supplying these master tissues with adequately-prepared food and oxygen, for cleansing them from the waste-products of their activity, and for keeping them at a temperature suitable for the development of their powers. As we have already said, the blood is the agent which not only supplies both food and oxygen but sweeps away all refuse, and, we may add, is the instrument for maintaining an adequate temperature. All the rest of the body may in fact be looked upon as busied in manufacturing food into blood, in keeping up the oxygen supply of the blood, in sifting out from the blood all waste material, and in maintaining the blood at a uniform heat. This work, of which blood is, so to speak, the centre, is, as we have already seen, carried out by protoplasmic cells, many of which are themselves of a muscular nature, often forming part of complicated mechanical

contrivances, built up partly of inert tissues, partly of active tissues, such as muscle and nerve. In tracing the food and oxygen into the blood and the waste matters out of the blood, in studying the distribution of the blood itself and the means adopted to maintain its even temperature, we come, as before, on problems partly mechanical or chemical and partly molecular. The changes which the food undergoes in the intestine can be, and have been, successfully studied as a series of purely chemical problems conditioned by anatomical arrangements, such as the existence of an acid fluid in the stomach, succeeded by alkaline fluids in the intestine, and the like; but the questions concerned in the discharge of the digestive juices into the alimentary canal, in the secretory activity of the digestive glands, raise up protoplasmic molecular inquiries. In the reception or absorption of the digested food we similarly find the purely physical processes of diffusion and the like overridden by the special protoplasmic activities of the constituent cells of the lining of the canal. In the further elaboration of the digested products the action of cells again intervenes, as it similarly does in the, so to speak, inverted action by which waste matters are cast out of the body, though in both cases the results are in part conditioned by mechanical contrivances. The circulation of the blood is carried on by means of an intricate mechanical contrivance, whose working is determined and whose effects are conditioned by molecular changes occurring in the constituent muscles and other protoplasmic cells; the work done by the heart, the varying width of the channels, the transit of material through the filmy capillary walls, all these are at once the results of protoplasmic activity and factors in the mechanical problems of the flow of blood. The oxygen passes into and carbonic acid out of the blood, through simple diffusion, by means of the respiratory pump, which is merely a machine whose motive-power is supplied by muscular energy, and both oxygen and carbonic acid are carried along in the blood by simple chemical means; but the passage of oxygen from the blood into the tissue and of carbonic acid from the tissue into the blood, though in themselves mere diffusion processes, are determined by the molecular activity of the constituent cells of the tissue. Lastly, the blood, however well prepared, however skilfully driven to the tissue by the well-timed activity of the vascular system, even when it has reached the inner network of the tissue-elements, is not as yet the tissue itself. To become the tissue it must undergo molecular changes of the profoundest kind: it must cross the boundary from dead material to living stuff. The ultimate problems of nutrition are of the molecular kind. All the machinery, however elaborate, is preparatory only, and it is the last step which costs the most.

Of the many problems concerned in these several departments of physiology the one class which we have spoken of as being mechanical in nature is far too varied to be treated of as a whole. The problems falling under it have but few features in common; each stands, as it were, on its own bottom, and has to be solved in its own way. The problems of the other class, however—those which we have spoken of as being molecular in nature—have a certain common likeness; and it may be worth while to consider, in a brief and general manner, some of their most striking characters.

For this purpose we may first of all turn to the changes taking place in a secreting cell, for these have of late years been studied with signal success. They illustrate what may be called the chemical aspects of vital actions, just as the changes in a muscular fibre, on the other hand, seem to present, in their simplest form, the kinetic aspects of the same actions. If we examine a secreting gland, such as a pancreas or a salivary gland, we find that it is

composed of a number of similar units, the unit being a secreting cell of approximately spheroidal form, one part of the surface of which borders a canal continuous with the duct of the gland, while another part is bathed in lymph. The process of secretion consists in the cell discharging into the canal a fluid which is of a specific character, inasmuch as, though it consists partly of water and other substances common to it and other fluids of the body, these are present in it in special proportions; and it also contains substances or a substance found in itself and nowhere else. To enable it to carry on this work the cell receives supplies of material from the lymph in which it is bathed, the lymph in turn being replenished from neighbouring capillary blood-vessels. The secreting cell itself consists of a soft protoplasmic "body," of the nature previously described, in the midst of which lies a "nucleus." The consideration of the actions carried out by the nucleus may, for simplicity's sake, be left on one side for the present; and we may regard the cell as a mass of protoplasm consisting, as we have seen, of a network of a particular nature, and of other substances of different nature filling up the meshes or interstices of the network.

Such a cell may exist under two different conditions. At one time it may be quiescent: although the blood-vessels surrounding it are bathing it with lymph, although this lymph has free access to the protoplasm of the cell, no secretion takes place, no fluid whatever passes from the cell into the canal which it borders. At another time, under, for instance, some influence reaching it along the nerve distributed to the gland, although there may be no change in the quantity or quality of the blood passing through the adjacent blood-vessels, a rapid stream of material flows from the protoplasmic cell-body into the canal. How is this secretion brought about?

If we examine certain cells, such, for instance, as those of the pancreas, we find that during a period of rest succeeding one of activity the cell increases in bulk, and further that the increase is not so much an enlargement of the protoplasmic network as an accumulation of material in the meshes of the network; in fact, there appears to be a relative diminution of the actual protoplasm, indicating, as we shall see, a conversion of the substance of the network into the material which is lodged in the interstices of the network. This material may, and frequently does, exist in the form of discrete granules, recognizable under the microscope; and in the pancreas there is a tendency for these granules to be massed together on the side of the cell bordering the lumen of the canal. During activity, while the cell is discharging its secretion into the canal, these granules disappear, so that the protoplasmic network is after prolonged activity left with a very small burden of material in its meshes; at the same time there also appears to be an accompanying absolute increase of growth of the mass of the protoplasm itself. We have further evidence that the substance which is thus stored up in the meshes of the cell, forming the granules, for instance, just spoken of, is not, as it exists in the cells, the same substance as that which occurs in the secretion as its characteristic constituent. Thus the characteristic constituent of pancreatic juice is a peculiar ferment body called "trypsin," and we possess evidence that the granules in the pancreatic cells are not trypsin. But we have also evidence that these granules consist of material which, upon a very slight change, becomes trypsin, of material which is an antecedent of trypsin, and which has accordingly been called "trypsinogen." Thus the cell during rest stores up trypsinogen, and the change which characterizes activity is the conversion of trypsinogen into trypsin, and its consequent discharge from the cell. These are facts ascertained by observation and experiment, viz., that trypsinogen appears

in the protoplasm of the cell, and that in the act of secretion this trypsinogen is discharged from the cell in the form of the simpler trypsin. When, however, we come to consider the origin of the trypsinogen we pass to matters of inference and to a certain extent of speculation.

Two views seem open to us. On the one hand, we may adopt an old theory, once generally accepted, and suppose that the cell picks out from the lymph which bathes it particles of trypsinogen, or particles of some substance which is readily transformed into trypsinogen, and deposits them in its substance. This may be called the "selective" theory. On the other hand, we may suppose that the trypsinogen results from the breaking down, from the katabolic or destructive metabolism of the protoplasm, being thus wholly formed in the cell. This may be called the "metabolic" theory. Our present knowledge does not permit us wholly to prove or wholly to disprove either of these theories; but such evidence as we possess is in favour, and increasingly in favour, of the metabolic theory. All efforts to detect in the blood or in the lymph such substances as trypsinogen, or analogous substances in the case of other glands, have hitherto failed; and, although such a negative argument has its weakness, still it is of avail as far as it goes. On the other hand, the diminution of the protoplasm in the pancreatic cell, *pari passu* with the increase of trypsinogen, and its subsequent renewal previous to the formation of new trypsinogen, strongly support the metabolic theory, and a number of other facts drawn from the history of various animal and vegetable cells all tend strongly in the same direction. We have further a certain amount of evidence that trypsinogen arises from an antecedent more complex than itself, as it in turn is more complex than trypsin. So, although clear demonstration is not as yet within our reach, we may with considerable confidence conclude that trypsinogen and other like products of secreting cells arise from a breaking down of the cell-substance, are manufactured by the protoplasm of the cell out of itself.

Meso-
states.

We are thus led to the conception that the specific material of a secretion, such as the trypsin of pancreatic juice, comes from the protoplasm of the cell, through a number of intermediate substances, or *mesostates* as they are called; that is to say, the complex protoplasm breaks down into a whole series of substances of decreasing complexity, the last term of which is the specific substance of the secretion. Now the protoplasm is undoubtedly formed at the expense of the material or pabulum brought to it from the blood through the medium of the lymph; the pabulum becomes protoplasm. Here also two views are open to us. On the one hand, we may suppose that the crude pabulum is at once by a magic stroke, as it were, built up into the living protoplasm. On the other hand, we may suppose that the pabulum reaches the stage of protoplasm through a series of substances of increasing complexity and instability, the last stage being that which we call protoplasm. And here, too, no absolute decision between the two views is possible, but such evidence as we do possess is in favour, and increasingly in favour, of the latter view.

We may therefore with considerable confidence anticipate the future arrival of evidence which will demonstrate the as yet only probable view that in the secreting cell there are two series of events, two staircases, as it were, of chemical transformation,—one an ascending staircase of synthetic, anabolic processes through which the pabulum, consisting of several substances, some of them already complex and unstable, is built up into the still more complex and still more unstable protoplasm; the other a descending staircase, consisting of a series of katabolic processes giving rise to substances of decreasing complexity and increasing

Ana-
states
and
kata-
states.

stability. The substances or mesostates appearing in the former we may speak of as "anastates," those of the latter we may call "katastates." At each step of the former, by which a simpler anastate becomes, or by which simpler anastates become, a more complex one, energy is absorbed; at each step of the latter energy is set free. And, since in the animal-cell the initial anastates seem always or at least generally more complex than the final katastates, the total life of the animal-cell is virtually a giving forth of energy.

So far we have spoken of the secreting cell, but we have evidence that in the activity of a muscle a similar series of events takes place. Reduced to theoretical simplicity, the unit a number of which go to form a muscle is a protoplasmic cell, undergoing, like the secreting cell, a continual metabolism, with a change in the results of that metabolism at the moment of functional activity. Put in a bald way, the main difference between a secreting cell and a muscle-cell, or elementary muscle-fibre as it is often called, is that in the former the products of the metabolism constitute the main object of the cell's activity, a change of form being of subordinate importance, whereas in the latter the change of form, an increase of one axis at the expense of another, a shortening with corresponding thickening, is the important fact, the products of the metabolism which thus gives rise to the change of form being of secondary value.

Now we have evidence, which, as in the case of the secreting cell, though not demonstrative, is weighty and of daily increasing weight, that the change of form, the contraction of a muscle, is due to a sudden metabolism, to an explosive decomposition of what may be called "contractile substance," a substance which appears to be used up in the act of contraction, and the consumption of which leads with other events to the exhaustion of a muscle after prolonged exertion. We know as a matter of fact that when a muscle contracts there is an evolution of a considerable quantity of carbonic acid, and a chemical change of such a kind that the muscle becomes acid. This carbonic acid must have some antecedent, and the acidity must have some cause. It is of course possible that the protoplasm itself explodes, and is the immediate parent of the carbonic acid and the direct source of the energy set free in the contraction; but evidence analogous to that brought forward in relation to the secreting cell leads to the conclusion that this is not so, but that the explosion takes place in, and that the energy is derived from, a specific contractile substance. And there is further evidence that this hypothetical substance, to which the name of "inogen" has been provisionally given, is, like its analogue in the secreting cell, a katastate. So that the contracting activity of a muscular fibre and the secreting activity of a gland-cell may be compared with each other, in so far as in each case the activity is essentially a decomposition or explosion, more or less rapid, of a katastate, the inogen in the one instance, the trypsinogen or some other body in the other instance, with the setting free of energy, which in the case of the secreting cell leaves the substance wholly as heat, but in the case of the muscle partly as movement, the activity being followed in each case by the discharge from the fibre or cell of the products, or some of the products, of this decomposition.

Further, we may carry on the parallel to nervous substance. As a nervous impulse travels along a nerve-fibre or pursues its intricate course along the fibrillar tracts of a nerve-cell, the amount of chemical change is too slight to be satisfactorily appreciated by the methods at present under our command. There is certainly no massive explosion like that of a muscular fibre, and the most striking phenomena attending the passage of a nervous impulse are

In ner-
vous sub-
stance.

of an electrical nature. We cannot indeed distinctly prove that any chemical change does really accompany nervous activity; but from many considerations it is extremely probable that a chemical change, an explosive decomposition of more complex into more simple substances, is the basis of a nervous impulse. The energy, however, which is set free by this decomposition is not discharged from the nervous substance to so great an extent as is the case in the muscle-fibre, but is largely consumed in conveying or conducting the decomposition from one particle of the nervous substance to succeeding ones,—that is to say, in carrying out that which is the essential work of the nervous substance. Moreover, even in a muscle, while the explosion of inogen and the consequent shortening and thickening of the muscle-substance travel along the fibre from particle to particle in the form of a wave starting from the junction of the nerve-fibre with the muscular fibre, or from some other point of stimulation, this wave of visible contraction is preceded by invisible molecular changes also travelling along the fibre in the form of a wave, changes which manifest themselves by no massive explosions, which are indicated by electrical phenomena chiefly, and which are exceedingly like the nervous impulses of proper nervous structures. In the very substance of the muscular fibre there appears to be a material which is not inogen, but which is capable of undergoing changes, probably of the nature of an explosive decomposition, and it is these which in turn induce the more massive decomposition of the inogen. It is possible, indeed probable, that the constituent particles of inogen are not able to communicate their explosions to each other, so that the presence in the muscular fibre of an impulse-carrying material is a necessity. Be this as it may, a change antecedent to the explosion which is the cause of the actual contraction does occur in every particle of the muscle which contracts, and, as we have urged, the change is probably one taking place in a special substance. This substance may be the veritable protoplasm itself of the fibre, but considerations analogous to those urged before would lead us to suppose that it too is a katastate, but a katastate different in qualities from inogen; and we may further suppose that a very similar katastate is manufactured by nervous protoplasm, and by its decomposition gives rise to nervous energy. This katastate is, as it were, the fuse or trigger whose action fires the massive charge of the muscular gun, and might receive the name of “apheter.”

Meta-
bolic
changes
in cen-
tral
nervous
system.

If we accept this view as to the nature of the simple nervous impulses which sweep along nerve-fibres—and in this respect motor and sensory nerves would seem wholly alike—there is no great difficulty in extending the conception to the more complicated processes taking place in the central nervous system. An ordinary reflex act, so called, is perhaps one of the simplest labours of that system, and we have evidence that in a reflex act sensory impulses arriving along a sensory fibre at the protoplasm of a nerve-cell induce in that protoplasm changes which, though in certain respects differing from, are fundamentally analogous to, those changes in motor and sensory nerve-fibres which constitute their respective nervous impulses. The chief difference is that, whereas along sensory and motor fibres the impulses pursue an even course, possibly undergoing some augmentation, but one which is not sufficiently marked to be beyond doubt, in the nerve-cell, on the contrary, an unmistakable augmentation accompanied by a systematic dispersion takes place. So great is the augmentation in some cases that a gentle short series of sensory impulses reaching one of a group of nerve-cells along a single sensory fibre may throw the whole group of nerve-cells into such profound agitation that repeated series of even violent impulses may be discharged along a multitude of

motor fibres. Allowing for this increase in the energy set free, the changes in the nerve-cells do not seem to differ fundamentally from those in the nerve-fibres (which indeed differ to a certain extent among themselves), and may, like them, be regarded as due essentially to the decomposition of some katastate or katastates.

Further, just as the aphetor of the muscular fibre, that which inaugurates the explosion of the contractile inogen, differs from the aphetor of the nerve-fibre, so we may suppose that in the various nerve-cells of different parts of the central nervous system difference of function, while partly due to the mere arrangement and distribution of nervous impulses of the same kind, is also and more largely due to difference in the kind of impulses brought about by difference in the composition and mode of decomposition of the nervous material. For instance, certain changes in the nervous system are accompanied by distinct changes of consciousness, while others are not. And, while we may justly refuse to attempt any explanation of consciousness, it is nevertheless within our right to suppose that, in that nervous substance which is the highest development of protoplasm and to whose service the whole body ministers, amid the many substances of increasing complexity and dignity which enter into its composition there should be a substance or some substances the changes in which are, or may be, accompanied by consciousness. The doctrine of evolution compels us to admit that consciousness must be potentially present in the simple protoplasm of the amœba, and must be similarly present in all the tissues of the highly-developed animal, instead of being confined to some limited portion of the nervous system. Evolution refuses to admit a sharp line of demarcation between a “conscious” and a “non-conscious” part, and this decision is increasingly supported as our knowledge of the nervous system advances. But a great deal of the earlier part of this article was directed to show that all the powers of the complex animal are the outcome of the differentiation of a primordial protoplasm, while the discussion concerning the molecular changes of tissues in which we are now engaged is simply an attempt to trace out how that differentiation has taken place. And, as far as we can see, there are no just reasons why the differentiation which sets apart the nervous tissue from other parts of the body should not obtain in the nervous tissue itself, and the obscure rudiments of consciousness present in all nervous material become by differentiation developed, in some particular kinds of nervous substance, into consciousness more strictly so called.

In the case, then, of secreting cells, of muscular tissue, and of the various forms of nervous tissue the tendency of inquiries into the molecular processes taking place in them is to lead us to regard the varied activities of these tissues as due to molecular disruptive changes in their several katastates, these being various stages of the downward metabolism or katabolism of protoplasm.

Similar considerations might be extended to other tissues of the body which are neither nervous nor muscular, and, though engaged in chemical work, are not distinctly secretory or excretory, such, for instance, as the hepatic cells engaged in the elaboration of glycogen. They might also be extended to those tissues in which the katastates are not exploded and discharged, but retained and massed up in the body for mechanical or other purposes, to cartilage, for instance, the chondrogenous basis or ground substance which many considerations show to be a product or katastate of protoplasm. We are thus led to the conception, brought forward in an earlier part of this article, that all over the body protoplasm is continually building itself up out of the pabulum supplied by food, and continually breaking down, giving rise in different tissues and

different parts of the body to different *katastates* with different composition and different properties, the various activities of the body being the outcome of the various properties of the various *katastates*. If this be admitted, it almost inevitably follows that what we have called protoplasm cannot be always the same thing, that there must be many varieties of protoplasm with different qualities and with correspondingly different molecular structure and composition. If this be so, the question naturally arises, why use the word protoplasm at all, since, by the showing, it seems to have no exact meaning? But it has an exact meaning. All the evidence at our disposal goes to show that a *katastate* of any given degree cannot form a fresh *katastate* of the same degree; any one *katastate* can only arise from the decomposition of a preceding more complex *katastate*, and that in turn from a *katastate* still more complex. Passing upwards, we come at last to something which, instead of proceeding from a more complex substance, builds itself up out of a less complex, more simple substance, and it is this something, whatever its exact composition, into whatever *katastates* it is destined to fall asunder, to which the generic name "protoplasm" should be given. Possibly another new name were better, but there are advantages in retaining the old term. It is protoplasm in this sense which is alone *living*; it is its synthetic power which is its token of being alive. That synthetic power is, we must admit, exercised along the ascending series of *anastates*. But here our knowledge is a blank; and it would be simply waste of time to speculate as to the details of the constructive processes. Using the word "protoplasm" in this sense, it is obvious that the varieties of protoplasm are numerous, indeed almost innumerable. The muscular protoplasm which brings forth a contractile *katastate* must differ in nature, in composition—that is, in construction—from glandular protoplasm, whose *katastate* is a mother of ferment. Further, the protoplasm of the swiftly contracting striped muscular fibre must differ from that of the torpid smooth unstriated fibre; the protoplasm of human muscle must differ from that of a sheep or a frog; the protoplasm of one muscle must differ from that of another muscle in the same kind of animal; and the protoplasm of Smith's biceps must differ from that of Jones's.

We may, for a moment, turn aside to point out that this innate difference of protoplasm serves to explain the conclusions to which modern investigations into the physiology of nutrition seem to be leading. So long as we speak of muscle or flesh as one thing, the step from the flesh of mutton which we eat to the flesh of our body which the mutton, when eaten, becomes, or may become, does not seem very far; and the older physiologists very naturally assumed that the flesh of the meal was directly, without great effort and without great change, as far as mere chemical composition is concerned, transformed into the muscle of the eater. The researches, however, of modern times go to show that the substances taken as food undergo many changes and suffer profound disruption before they actually become part and parcel of the living body, and conversely that the constructive powers of the animal body were grossly under-rated by earlier investigators. If one were to put forward the thesis that the proteid of a meal becomes reduced almost to its elements before it undergoes synthesis into the superficially similar proteid of muscle, the energy set free in the destruction being utilized in the subsequent work of construction, he might appeal with confidence to modern results as supporting him rather than opposing him in his views. It would almost seem as if the qualities of each particle of living protoplasm were of such an individual character that it had to be built up afresh from almost the very beginning; hence the im-

mense construction which inquiry shows more and more clearly every day to be continually going on as well in the animal as in the vegetable body.

Taking into consideration all the fine touches which make up the characters of an individual organism, and remembering that these are the outcome of the different properties or activities of the several constituent tissues of the body, working through a delicately-balanced complicated machinery, bearing in mind the far-reaching phenomena of heredity by which the gross traits and often the minute tricks of the parents' body are reproduced in the offspring, if there be any truth at all in the views which we have urged, tracing the activities of the organism to the constitution of its protoplasm, this must be manifold indeed. The problems of physiology in the future are largely concerned in arriving, by experiment and inference, by the mind's eye, and not by the body's eye alone, assisted as that may be by lenses yet to be introduced, at a knowledge of the molecular construction of this protean protoplasm, of the laws according to which it is built up, and the laws according to which it breaks down, for these laws when ascertained will clear up the mysteries of the protean work which the protoplasm does.

And here we may venture to introduce a word of caution. We have, in speaking of protoplasm, used the words "construction," "composition," "decomposition," and the like, as if protoplasm were a chemical substance. And it is a chemical substance in the sense that it arises out of the union or coincidence of certain factors, which can be resolved into what the chemists call "elements," and can be at any time by appropriate means broken up into the same factors, and indeed into chemical elements. This is not the place to enter into a discussion upon the nature of so-called chemical substances, or, what is the same thing, a discussion concerning the nature of matter; but we may venture to assert that the more these molecular problems of physiology, with which we are now dealing, are studied the stronger becomes the conviction that the consideration of what we call "structure" and "composition" must, in harmony with the modern teachings of physics, be approached under the dominant conception of modes of motion. The physicists have been led to consider the qualities of things as expressions of internal movements; even more imperative does it seem to us that the biologist should regard the qualities (including structure and composition) of protoplasm as in like manner the expression of internal movements. He may speak of protoplasm as a complex substance, but he must strive to realize that what he means by that is a complex whirl, an intricate dance, of which what he calls chemical composition, histological structure, and gross configuration are, so to speak, the figures; to him the renewal of protoplasm is but the continuance of the dance, its functions and actions the transferences of figures. In so obscure a subject it is difficult to speak otherwise than by parables, and we may call to mind how easy it is to realize the comparison of the whole body of man to a fountain of water. As the figure of the fountain remains the same though fresh water is continually rising and falling, so the body seems the same though fresh food is always replacing the old man which in turn is always falling back to dust. And the conception which we are urging now is one which carries an analogous idea into the study of all the molecular phenomena of the body. We must not pursue the subject any further here, but we felt it necessary to introduce the caution concerning the word "substance," and we may repeat the assertion that it seems to us necessary for a satisfactory study of the problems on which we have been dwelling for the last few pages to keep clearly before the mind the conception that the phenomena in question are the result not of properties of kinds of

matter, in the vulgar sense of these words, but of kinds of motion.

In the above brief sketch we have dealt chiefly with such well-known physiological actions as secretion, muscular contractions, and nervous impulses. But we must not hide from ourselves the fact that these grosser activities do not comprise the whole life of the tissues. Even in the simple tissues, and more especially in the highly-developed nervous tissues, there are finer actions which the conception outlined above wholly fails to cover.

Finer
activities
of proto-
plasm.

Two sets of vital phenomena have hitherto baffled inquirers,—the phenomena of spontaneous activity, rhythmic or other, and the phenomena of “inhibition.” All attempts to explain what actually takes place in the inner working of the tissues concerned when impulses passing down the pneumogastric nerve stop the heart from beating, or in the many other analogous instances of the arrest of activity through activity, have signally failed; the superficial resemblance to the physical “interference of waves” breaks down upon examination, as indeed do all other hypotheses which have as yet been brought forward. And we are wholly in the dark as to why one piece of protoplasm or muscular fibre or nervous tissue remains quiescent till stirred by some stimulus, while another piece explodes into activity at rhythmic intervals. We may frame analogies and may liken the phenomena to those of a constant force rhythmically overcoming a constant resistance, but such analogies bring us very little nearer to understanding what the molecules of the part are doing at and between the repeated moments of activity.

Hering's
specula-
tions.

Further, if the ingenious speculations of Hering, that specific colour-sensations are due to the relation of assimilation (anabolism) to dissimilation (katabolism) of protoplasmic visual substances in the retina or in the brain, should finally pass from the condition of speculation to that of demonstrated truth, we should be brought face to face with the fact that the mere act of building up or the mere act of breaking down affects the condition of protoplasm in other ways than the one which we have hitherto considered, viz., that the building up provides energy to be set free and the breaking down lets the energy forth. In Hering's conception the mere condition of the protoplasm, whether it is largely built up or largely broken down, produces effects which result in a particular state of consciousness. Now, whatever views we may take of consciousness, we must suppose that an affection of consciousness is dependent on a change in some material. But in the case of colour-sensations that material cannot be the visual substance itself, but some other substance. That is to say, according to Hering's views, the mere condition of the visual substance as distinct from a change in that condition determines the changes in the other substance which is the basis of consciousness. So that, if Hering's conception be a true one (and the arguments in favour of it, if not wholly conclusive, are at least serious), we are led to entertain the idea that, in addition to the rough propagation of explosive decompositions, there are continually passing from protoplasm to protoplasm delicate touches compared with which the nervous impulses which with such difficulty the galvanometer makes known to us are gross and coarse shocks. And it is at least possible, if not probable (indeed present investigations seem rapidly tending in this direction), that an extension of Hering's view, with such modifications as future inquiry may render necessary, to other processes than visual sensations, more especially to the inner working of the central nervous system, may not only carry us a long way on towards understanding inhibition and spontaneous activity but may lay the foundation of a new molecular physiology. This, however, is speculative and dangerous ground. But it seemed

desirable to touch upon it since it illustrates a possible or probable new departure. What we have said of it and of the more manageable molecular problems of physiology will perhaps show that, vast and intricate as is the maze before the physiologist of to-day, he has in his hand a clue which promises, at least, to lead him far on through it.

Space forbids our entering upon a discussion concerning the methods of physiology; but, accepting the truth of the preceding discussion as to the nature of physiological problems, the means of solving these problems speak for themselves.

Methods
of phy-
siology.

From the earliest times the methods of physiological inquiry have belonged to one of two categories: they have been anatomical or experimental. And the same distinction holds good to-day, though both methods are often joined together in one inquiry, and indeed at times may be said to merge the one into the other. By the anatomical method the observer ascertains the gross outlines, the minute structure, and if necessary the physical characters and the chemical composition of an organism or part of an organism; and by comparison of these with those of different organisms, or of the same organism placed by nature—that is, not by himself—in different circumstances, he draws conclusions as to the actions taking place in it while it was alive. In early times the comparison of gross structures gave important results, but they have now been to a great extent exhausted; and the most valuable conclusions reached at the present day by the anatomical method are those arrived at by histological investigation of minute structures and by chemical analysis. The marks of this method are that on the one hand it deals for the most part with things which are no longer alive, and hence must necessarily fail to make touch with the inner workings of which we have spoken above, and on the other hand in its comparison of organisms under different conditions it has to wait till Providence brings about what it requires, and has to be satisfied with such differences as the chapter of accidents provides. In the experimental method the observer places the organism or part of the organism under conditions of his own choosing, and applies to the organism under those conditions the same analysis as in the former methods. He ascertains changes in the gross features, minute structure, physical characters, and chemical composition, as before. So that in reality the two methods are in part identical, and differ chiefly by the fact that in the latter the observer chooses the conditions in which to place the organism. But an important corollary follows, viz., that by choosing his own conditions the observer is able to bring his analysis to bear on an organism or part of an organism while still alive.

The history of physiology, especially in recent times, shows that this method is the one not only of the greatest fertility but one becoming more and more essential as inquiry is pushed deeper and deeper into the more abstruse parts of physiology. If there be any truth in the sketch given above of the modern tendencies of molecular physiology, it will be clear to every mind that the experimental method alone can in the future give adequate results. It might indeed be urged that when molecular physics has advanced far enough the molecular problems of physiology will be interpreted by its light without recourse to experiment. It will be a long waiting till that comes. Meanwhile, all the power over not only the body but, what is more important, the mind of man which the physiology of the future unmistakably promises must lie unused. Nor is it simply a matter of waiting, for it is at least within the range of possibility that when the molecular problems of physiology are fairly grasped conclusions may be reached which will throw back a light on the molecular processes of inanimate masses, revealing features of what we call

"matter" which could not be discovered by the examination of bodies which had never lived.

Value of
experi-
mental
method.

It would not be a hard task to give chapter and verse for the assertion that the experimental method has, especially in these later times, supplied the chief means of progress in physiology; but it would be a long task, and we may content ourselves with calling attention to what is in many respects a typical case. We referred a short time back to the phenomena of "inhibition." It is not too much to say that the discovery of the inhibitory function of certain nerves marks one of the most important steps in the progress of physiology during the past half-century. The mere attainment of the fact that the stimulation of a nerve might stop action instead of inducing action constituted in itself almost a revolution; and the value of that fact in helping us on the one hand to unravel the tangled puzzles of physiological action and reaction, and on the other hand to push our inquiries into the still more difficult problems of molecular changes, has proved immense. One cannot at the present time take up a physiological memoir covering any large extent of ground without finding some use made of inhibitory processes for the purpose of explaining physiological phenomena.

Now, however skilfully we may read older statements between the lines, no scientific—that is, no exact—knowledge of inhibition was possessed by any physiologist until Weber, by a direct experiment on a living animal, discovered the inhibitory influence of the pneumogastric nerve over the beating of the heart. It was of course previously known that under certain circumstances the beating of the heart might be stopped; but all ideas as to how the stoppage was or might be brought about were vague and uncertain before Weber made his experiment. That experiment gave the clue to an exact knowledge, and it is difficult, if not impossible, to see how the clue could

have been gained otherwise than by experiment; other experiments have enabled us to follow up the clue, so that it may with justice be said that all that part of the recent progress of physiology which is due to the introduction of a knowledge of inhibitory processes is the direct result of the experimental method. But the story of our knowledge of inhibition is only one of the innumerable instances of the value of this method. In almost every department of physiology an experiment or a series of experiments has proved a turning-point at which vague nebulous fancies were exchanged for clear decided knowledge, or a starting-point for the introduction of wholly new and startling ideas. And we may venture to repeat that not only must the experimental method be continued, but the progress of physiology will chiefly depend on the increased application of that method. The more involved and abstruse the problems become, the more necessary does it also become that the inquirer should be able to choose his own conditions for the observations he desires to make. Happily, the experimental method itself brings with it in the course of its own development the power of removing the only valid objection to physiological experiments, viz., that in certain cases they involve pain and suffering. For in nearly all experiments pain and suffering are disturbing elements. These disturbing elements the present imperfect methods are often unable to overcome; but their removal will become a more and more pressing necessity in the interests of the experiments themselves, as the science becomes more exact and exacting, and will also become a more and more easy task as the progress of the science makes the investigator more and more master of the organism. In the physiology of the future pain and suffering will be admissible in an experiment only when pain and suffering are themselves the object of inquiry. And such an inquiry will of necessity take a subjective rather than an objective form. (M. F.)

PART II.—NERVOUS SYSTEM.

To supplement the foregoing general sketch some detailed account must be given of the physiology of the several functions. NUTRITION (g.v.) has received separate treatment; a sketch of the "Nervous System" is now appended; and RESPIRATION and REPRODUCTION will be dealt with in their places.

However complex may be the anatomical arrangements in man and the higher animals, the nervous system consists essentially of three portions: (1) *central masses* of nervous matter, or *ganglia*, constituting the brain and spinal cord, and containing invariably nerve-cells; (2) *peripheral or terminal* arrangements, existing in the organs of sense, in muscle, and in electric organs; and (3) *nerves*, or internuncial cords connecting the central with the peripheral organs. The nerves may be regarded as conductors of a mode of energy which, for want of a better term, is termed "nerve-force," originating either in the nerves themselves on the application of a stimulus or in the terminal organs or in the central organs. Thus, if a nerve be irritated at any point of its course, a change is set up in the nerve-fibres at the point of irritation, and this change is propagated along the nerve-fibres to a central or terminal organ, thus producing a characteristic phenomenon,—it may be a sensation of pain or of pleasure, an involuntary movement, the contraction of a muscle, or a discharge of electricity. Again, the stimulus may act on a terminal organ, such as the retina, setting up a change which is then propagated or conveyed to the brain by the optic nerve, there giving rise to a sensation of light or colour. Finally, the nervous action may originate in a central organ, as is the case when a voluntary movement is made. The voluntary impulse, in this instance, originates in the brain; a change passes along nerve-fibres from the brain to the muscles, and as a result the muscles contract. We have therefore to discuss the general properties and modes of action of nerves, terminal organs, and central organs.

1.—NERVES.

Struc-
ture of
nerves.

Structure of Nerves.—A general description of the structure of nerves and of nerve-fibres will be found in vol. i. p. 859 *sq.*; but there are a few points of physiological importance still to be noticed. Two kinds of nerve-fibres exist in the body, white or medullated fibres, so called because each fibre has a sheath indicated by a double contour (see fig. 1), and the pale or non-medullated. The medullated nerve-fibres form the white part of the

brain, spinal cord, and nerves. They vary in diameter from the $\frac{1}{1000}$ th to the $\frac{1}{100}$ th of an inch, and when of very small size often show varicosities or swellings. Each fibre consists of three parts:

(1) an external sheath, or primitive sheath; (2) within this the medullary sheath or white substance of Schwann; and (3) in the centre an axial fibre, the cylinder axis of Purkinje, or band of Remak. The axis-cylinder in a fresh nerve seems to be homogeneous; but with high powers and proper illumination, and more especially

Fig. 1.

Fig. 2.

Fig. 1.—(1) Medullated nerve-fibres, showing double contour; (2) a similar fibre in which A is primitive membrane, B medullary sheath, C axial cylinder protruding beyond the broken end of the fibre; (3) transverse section through medullated fibres of a nerve showing axial cylinder in each fibre. Between the fibres is the interfibrillar connective tissue.

Fig. 2.—Medullated nerve-fibres. A, medullated nerve-fibre, showing sub-division of medullary sheath into cylindrical sections imbricated with their ends; a nerve-corpuscle with an oval nucleus is seen between neurilemma and medullary sheath; B, medullated nerve-fibre at a node or constriction of Ranvier; the axis-cylinder passes uninterruptedly from one segment into the other, but the medullary sheath is interrupted. (Key and Retzius.)

by the action of perosmic acid, it is seen to be formed of extremely fine fibrille. It is continuous from end to end of the nerve. The medullary sheath shows at certain intervals interruptions called the "nodes of Ranvier" (see fig. 2). In the middle of each internode an oval nucleus is found in the medullary sheath. The pale or non-medullated fibres, sometimes called the "fibres of

Remak," are found chiefly in branches of the sympathetic nerve. They have no double contour, and they often give off branches which anastomose, a condition never found in the course of medullated nerves. If the axis-cylinder of a nerve-fibre be traced inwards to a nerve-centre it is found to end in the pole or process of a nerve-cell, whilst in the periphery it ends in a terminal organ, in muscle, blood-vessel, gland, skin, or electric organ. It may therefore be presumed that the axis-rod is the conducting and so far the essential constituent of the nerve-fibre.

Chemical constitution.—Little is known of the chemical constitution of the nerve-fibre. The medullary matter contains fatty substances such as lecithin ($C_{44}H_{96}NPO_8$). The axis-rod appears to contain albuminous substances. Cholesterin ($C_{26}H_{44}O + H_2O$) and creatin ($C_4H_7N_3O_2$) have been obtained from nerves along with a small amount of gelatin and a horny matter, neurokeratin (Hermann). Nerves contain about 30 per cent. of water. Their reaction to test-paper is neutral. Nothing is known regarding the chemical changes occurring in a nerve-fibre during a state of activity, nor of the chemical products formed at that time. It has been stated that a nerve becomes acid after death (Funke).

As to the micro-chemistry of the nervous elements, it may be stated that the axis-cylinder contains an albuminous substance different from myosin; it gives a red colour on boiling with Milton's reagent (an acid nitrate of mercury); it is dissolved in weak solutions of ammonia, caustic potash, and chloride of sodium; it is hardened by solutions of chromic acid, bichromate of potash, and corrosive sublimate; it reduces the chloride of gold; and it shows transverse markings on the action of nitrate of silver. The white substance of Schwann is blackened by perosmic acid and is soluble in alcohol, ether, and oil of turpentine, thus showing its fatty character. The primitive sheath is a substance of a collagenous nature, that is, it yields gelatin on boiling. According to some, digestion in gastric or pancreatic juice leaves an insoluble matter like that found after the digestion of corneal or epidermic tissues, and hence called "neurokeratin."

Excitability.—The special property of a nerve-fibre is termed "excitability." Every kind of living protoplasmic matter is irritable,—that is, it responds in some way to a stimulus. Thus, if a morsel of protoplasm, such as an amoeba or a cartilage-cell or a white blood-corpusele, be stimulated mechanically or by shocks of electricity, it will contract or change its form. Again, if living muscular fibre be thus stimulated it also will contract. This property of responding to a stimulus is termed "irritability"; and in the structures mentioned the property is manifested by movement as the obvious phenomenon, but it is well known that more obscure phenomena follow the application of the stimulus. In the case of living nerve there is irritability also,—that is, the nerve responds to a stimulus; but in a portion of isolated nerve no change is visible. If, however, the nerve be connected at one end with its appropriate central or terminal organ we may have evidence of something having been transmitted along the nerve. Thus there may be sensation or movement, or both. Nerves are more irritable than contractile matter, and the term "excitability" is applied to the special irritability of nerve. The same strength of stimulus will act more powerfully on a nerve than on a muscle (Rosenthal). The use of the term "property" in physiology does not imply the idea of any kind of inherent force or entity, but simply that, in the case of muscle and nerve, irritation is followed by certain phenomena seen only in living matter.

(1.) The excitability of nerves is affected by certain conditions. Injury to the nerve, the application of caustics, and drying quickly destroy it. When a nerve is divided the excitability is increased for a short time, then rapidly diminishes, and finally disappears near the point of section. The end of the nerve still connected with central organs undergoes these changes in excitability more quickly than the portion cut off. As shown by Augustus Waller, when a nerve is separated from its central organ, such as the grey matter of the spinal cord for the motor roots, and the ganglia on the posterior roots for the sensory roots, the end of the nerve separated from the centre undergoes fatty degeneration. If, however, the cut ends of the nerve be brought into accurate contact, union soon takes place. Surgeons have frequently observed a return of sensibility to a part within a few days after the sensory nerve had been divided and the cut ends again brought into contact. Continued or excessive activity of a nerve soon lowers and may abolish excitability, thus producing exhaustion. On the other hand, a lengthened period of absolute repose lowers excitability, and if the nerve be inactive beyond a certain time it wastes, becomes thinner, and fatty degeneration occurs in its substance. Heat increases, whilst cold diminishes, excitability. In the case of frogs' nerves temperatures above $45^{\circ}C$. destroy excitability the more rapidly as they approach 70° , at which point it is almost instantaneously destroyed. Below 45° a rise of temperature first increases and then diminishes excitability, and it has been observed that whilst increasing its intensity it diminishes its duration (Afanasieff, Hermann). Finally, a diminished supply of blood quickly causes a fall of excitability.

Stimuli of nerves. (2.) Nerves may be excited by various kinds of stimuli: (a) mechanically, as by intermittent pressure, beating, section, pricking, &c.; (b) thermally, by variation of temperature; (c) chemically, by the application of such substances as acids, alkalis, or metallic

salts; (d) electrically, by continuous or induced currents; and (e) normally, by changes in the central or terminal organs. Mechanical irritation is applied during life when the trunk of a nerve is pressed upon. Radiant heat acts on the nerves of the skin, or heat may be applied by conduction from a hot body in contact with the surface. Little is known as to the specific effects of heat on the nerves of the human being. In the frog it has been found that a temperature of from 34° to $45^{\circ}C$. stimulates the motor nerves; about $40^{\circ}C$. sudden alterations of temperature may cause twitching of the connected muscles (Hermann). Many chemical substances in sufficient concentration will quickly destroy a nerve; but if they are in weak solutions the result may be stimulation. Thus, concentrated solutions of the mineral acids, alkalis, alkaline salts, concentrated lactic acid, and concentrated glycerin may act as strong stimulants (Kühne).

(3.) The influence of electrical stimulation of nerves demands more elaborate description. The effects, as already indicated, can be observed only when the nerve is connected with a muscle or with a central organ. In the first case electrical stimulation is followed by contraction of the muscle, in the second by a sensation if the central organ is the brain. Consequently we have to consider the phenomena following electrical stimulation (a) of a motor nerve and (b) of a sensory nerve.

(a.) *Electrical Stimulation of a Motor Nerve.*—A perfectly constant current of electricity, of moderate quantity and intensity, trical flowing through a portion of nerve produces no evident effect on stimulate the muscle, but any variation in the intensity or density of the current causes irritation, and the muscle gives a twitch. The motor effect is most apparent when the current is allowed to flow into nerve. the nerve and when it is suddenly cut off, or, in other words, at the moment of opening and of closing the circuit. The rapidity with which the variation in the density of the current is effected also has an important influence. Thus the shocks of frictional electricity stimulate strongly, because, although the amount of electricity is small, the currents are extremely rapid in appearing and disappearing. In like manner the quick shocks from induction-coils produced by rapidly opening and closing the primary circuit are strongly stimulating. Again, a very powerful current may pass through a nerve without exciting it, if it pass gradually. Occasionally a very weak current sent through a portion of nerve will cause a contraction, whilst a very strong current may fail to do so. In fact, the phenomenon of contraction of a muscle is influenced (a) by the direction and (b) by the strength of the current sent through the nerve. When the current is transmitted from the muscle in the direction of the spinal cord it is called an "upward" or "centripetal" current, when from the cord in the direction of the muscle it is called a "downward" or "centrifugal" current. Its strength is graduated by employing small Grove's cells, one cell giving a weak current, two or three giving a medium current, and four to six or seven a strong current. To graduate its amount more precisely resistance-coils may be introduced into the circuit, or we may employ a rheochord, by which a portion of the current is shunted back to the battery, whilst the remainder is allowed to pass to the nerve. In the circuit a key or interrupter is interposed, and so arranged that when the key is opened the current is broken or interrupted, and when the key is closed the circuit is completed and the current passes to the nerve. With these arrangements, and employing the sciatic nerve of a frog attached to the limb, the following results are readily obtained.

Current Strength.	Key.	Upward Current.	Downward Current.
Weak.	Close.	Contraction.	Contraction.
Weak.	Open.	Rest.	Rest.
Medium.	Close.	Strong contraction.	Strong contraction.
Medium.	Open.	Strong contraction.	Strong contraction.
Strong.	Close.	Rest.	Rest.
Strong.	Open.	Very strong contraction.	Contraction.

That is to say, on beginning with a very feeble current neither opening nor closing causes a contraction, but on strengthening it up to a certain point contraction appears first on closing, whilst opening produces no effect. By increasing the strength of the current a contraction is obtained both on opening and on closing the key, and by and by, when a certain strength of current is reached, the closing contraction becomes weaker and finally disappears, leaving only a contraction on opening the key. Thus the effects of a strong current are usually the reverse of those caused by a weak current. These facts, usually included under the term "Pflüger's Law of Contraction," have been specially investigated by Pflüger, and the following is the explanation offered by him and generally accepted by physiologists.

Suppose that the sciatic nerve of a frog connected with the isolated limb is stretched over two wires passing from the positive and negative poles of a combination of Grove's elements, with the distance of an inch and a half between the wires. If a key be interposed in the circuit a current will thus pass along one and a half inches of nerve when the key is closed, and be cut off when the key is opened. By having also a commutator or reverser in the circuit we can send the current up or down the nerve at pleasure. Arrangements can also be made for irritating the nerve by another couple of wires coming from an induction-machine, either near the negative or near the positive pole of the current coming from the Grove's elements. It will then be found that near the negative pole the excitability of the nerve is increased, whilst near the

positive pole it is diminished,—that is to say, a stimulus from the induction-coil, not sufficient to excite the nerve so much as to cause a muscular contraction if applied near the positive pole, will at once do so if applied near the negative pole; or, a stimulus so strong as to cause tetanus in the muscle when applied near the negative pole may produce no effect when applied near the positive pole. In other words, the nerve near the negative pole is more excitable than in the normal state, whilst near the positive pole it is less so, indicating that at least one of the physiological properties of the nerve has been changed by the action of the continuous current. But a nerve-fibre has also the property of conducting the effects of an impression, or the nerve-force travels with a certain velocity along a nerve, as will be shown lower down. It has been ascertained that near the negative pole the rate of conductivity is increased, whilst near the positive pole it is diminished. Finally, a piece of living nerve, when connected with the terminals of a galvanometer, so that the one terminal touches the surface whilst the other touches the transverse section of the nerve, shows the existence of a current of electricity travelling from the surface of the nerve through the galvanometer to the transverse section,—that is, the surface is positive to the transverse section. This condition is also modified by the transmission through the nerve of a continuous current, so that the difference of potential is increased near the positive pole and diminished near the negative. These results are thus summed up.

State of Nerve.	Functions of Nerve.		
	<i>Electromotive force.</i>	<i>Conductivity.</i>	<i>Excitability.</i>
Near positive pole	Increased	Diminished	Diminished
Near negative pole	Diminished	Increased	Increased

The properties of the nerve, therefore, are altered by the passage through it of a continuous current, and the altered condition is termed the "electrotonic state," the condition in the neighbourhood of the positive pole, or anode, being termed "anoelectrotonic," whilst that near the negative pole or katode is called "katelectrotonic." A certain portion of nerve near each pole is thrown during the passage of a continuous current into these conditions of anoelectrotonus and of katelectrotonus, whilst the amount of nerve thrown into the one condition or the other depends on the strength of the current. Further, there is always between the two poles a point of indifference, in which the properties of the nerve seem to be unaltered, and the position of this point depends on the strength of the current. Thus, with a current of medium strength the point is midway between the poles; with a weak current the point is near the positive pole,—that is, a large portion of the nerve near the negative pole is in the katelectrotonic state in which the excitability is increased; and with a strong current the point is near the negative pole,—that is, a large portion of the nerve near the positive pole is in the anoelectrotonic state in which the excitability is diminished. Now, according to Pflüger, the stimulating effect of closing the current occurs at the katode only, whilst the stimulating effect of opening the current occurs at the anode only, or a nerve is stimulated by a current on the appearance or increase of katelectrotonus, on closing the circuit, or by the disappearance or diminution of anoelectrotonus on opening the circuit. If we suppose that this depends on the modification of excitability near the negative pole, by the molecules of the nerve becoming more mobile, the matter is intelligible. Thus the passage of the molecules from the normal stable condition to the katelectrotonic less stable condition acts as a stimulus, whilst the passage backwards has no effect. On the other hand, the passage from the more stable condition in anoelectrotonus to the normal stable condition acts as a stimulus, whilst, again, the reverse action has no effect. This explains why it is that a weak current gives contraction on closing, because on closing a large portion of the nerve near the negative pole passes from the normal into the katelectrotonic state, and this acts as a stimulus. On the other hand, a strong current causes contraction on opening, because on opening a large portion of nerve near the positive pole passes back from the anoelectrotonic state into the normal state, and this acts as a stimulus. Again, with currents of medium strength, as both states are equally produced, there is contraction both on opening and on closing. Thus Pflüger's theory accounts for most of the facts; but its weak point is that no reason can be given why a nerve is stimulated only by the appearance of katelectrotonus and by the disappearance of anoelectrotonus. It remains only to add that currents passing transversely through nerves produce no stimulating effect. In ascending currents the shorter the piece of nerve between the electrodes the greater the stimulating effect, whereas in descending currents the reverse holds good (Hermann).

Electrical stimulation of sensory nerves.

(b.) *Electrical Stimulation of Sensory Nerves.*—The effect of stimulating sensory nerves as distinguished from the direct stimulation of sensory or terminal organs has not been sufficiently studied, but, so far as is known, the laws seem to be the same as those relating to motor nerves. When a sensory nerve is stimulated the test must be the resulting sensation. As stimulation of the motor nerve in the condition of anoelectrotonus or of katelectrotonus may or may not be followed by a contraction, so stimulation of the sensory nerve may or may not be followed by a sensation, or the character of the sensation may vary just as the muscular contraction may be weak or strong. Further, Donders has shown that electrical stimulation of the vagi or pneumogastric nerves is attended by analogous phenomena, so far as the movements of the heart are concerned. In this case, however, as will be shown lower down in discussing the phenomena of nervous inhibition, the result is not movement but arrest of movement.

Unipolar excitation.

(c.) *Chauveau's Researches on Unipolar Excitation.*—Chauveau has studied the comparative influence of the two poles of any arrangement supplying a continuous current,—that is, he has tried the stimulating effect, supposing either the positive or the negative pole be applied to the nerve whilst the other is in contact with another part of the body. He has found, amongst other more abstruse and less practical results, that there is in each case a certain intensity of current corresponding to the physiological condition of the nerve by which the influence of one pole is the same as that of the other. If the intensity of the current be below this medium strength the effect of the negative pole on motor nerves is greater than that of the positive; but, if the intensity be above, the reverse is the case,—that is, the positive pole is the stronger excitant. In the case of sensory nerves Chauveau found that application of the negative pole with a moderately strong current was more painful than application of the positive pole. Thus the influence of unipolar

excitation with a strong current on motor nerves is the reverse of that on sensory nerves,—that is, the positive pole is the more powerful on motor nerves, the negative pole on sensory nerves.

(d.) *Production of Tetanus.*—Tetanus or cramp of a muscle is produced when its nerve is stimulated by successive irritations of at intervals so short that the muscle has no time to relax between tetanus, them, and consequently it passes into a state of more or less firm contraction. A single muscular contraction may be called a twitch of the muscle, but in tetanus or cramp the individual contractions are fused together so as to maintain a rigid state of the muscle for some time. A rapid series of induction shocks, each of short duration, always produces tetanus, even if they are sent to the muscle at the rate of 15 per second. A continuous current, on the other hand, usually causes contraction only at the moment of opening and closing the circuit, but occasionally tetanus may be seen during the passage of the current. Tetanus during the passage of a constant current has been attributed to electrolytic changes in the nerve. Pflüger holds that this is a normal production of tetanus and may be seen even with feeble currents; but certainly it is very difficult to demonstrate. Long ago Ritter showed that, if a constant current of sufficient intensity be sent up a nerve for a considerable time, say half an hour, and then be suddenly interrupted, tetanus lasting for eight or ten seconds may be seen, which disappears on again closing the current. Ritter's tetanus, according to Pflüger, is really due to the stimulation caused by the disappearance of anoelectrotonus, which occurs, as we have seen, when the current is opened, and the proof he offers is that the tetanus disappears when the muscle is cut off from the anoelectrotonic portion. Tetanus may also be caused by the mechanical irritation of the nerve, or by heat, or by chemical substances.

Nervous Conductivity.—When a nerve is irritated at any point in its course a change is produced which is propagated along the conductive nerve,—that is, the nerve conducts, and the phenomenon is called *ivity*. The "nerve-current." The velocity of transmission can be measured only by the use of delicate apparatus, as the time occupied is too short to directly affect consciousness. For example, when the tip of the finger is touched the mind apparently perceives the contact without any loss of time. But it can be shown that an appreciable interval of time elapses between the instant the finger is touched and the instant the mind perceives the impression. During this time a change passes along the nerve from the point touched to the brain. The method usually employed for determining the velocity of the nerve-current consists in preparing the gastrocnemius muscle of a frog with the sciatic nerve attached, and connecting it with a recording apparatus, so that if the muscle be caused to contract by irritating the nerve the record of the contraction may be made on a rapidly-moving surface. If, then, the nerve be irritated in two consecutive experiments, first close to the muscle, and secondly at a distance from it, and the muscle be caused to contract in each case, it will be found that it does not contract so soon when the nerve is irritated at a distance from the muscle as when it is irritated close to it; in other words, if the nerve be irritated at a distance from the muscle the transmission of the nervous impression from the point irritated to the muscle occupies an appreciable time. If, then, we know the length of nerve between the two points irritated, we can determine the length of time the nerve-current took in passing along that distance of nerve.

(1.) *Measurement of Velocity in Motor Nerves.*—Many ingenious methods have been devised for this purpose, but the simplest is the use of the "spring myograph" of Du Bois-Reymond (see fig. 3). The apparatus consists of a smoked-glass plate, which is driven in front of the recording stylus of the myograph by the recoil of a steel spring C. Underneath the frame carrying the glass plate are two binding screws 1 and 2, to one of which is attached a rectangular arm of brass 1, which can so move horizontally as to establish metallic connexion between the two binding screws (marked Break, F). By means of these binding screws the myograph is interposed in the circuit of a galvanic element and the primary coil I of an induction-machine, and the brass arm is so placed as to connect both binding screws, thus completing the circuit. From underneath the frame carrying the smoked-glass plate there descends a small flange, which (when the glass plate, by releasing a catch not seen in the figure, but close to C, is driven across by the spiral spring from left to right) pushes the brass arm aside and thus interrupts the circuit of the primary coil. When this occurs an opening shock is transmitted from the secondary coil II to a commutator B, an instrument by which electric currents may be transmitted to the nerve either at a point close to the muscle at A, or at a distance from it at B. Suppose the apparatus all arranged so as to send the shock to the nerve at a point close

FIG. 3.—Diagram showing arrangement of apparatus in measuring rapidity of nerve-current.

to the muscle A, the muscle stimulated contracts, and draws by means of the stylet, on the smoked surface of the glass, the curve seen in the lower part of it at A. This leaves the horizontal line (which would be drawn by the stylet were the muscle at rest) at A. Arrangements are then made for another experiment, in which the nerve will be stimulated at a distance from the muscle, at the point B in the upper part of the diagram. This is done by again placing the smoked-glass plate in proper position, closing the primary circuit by the brass arm at the binding screws, as already described, and reversing the commutator so as to send the shock along the wires to B. The muscle again contracts when the primary circuit is opened, and this time it describes on the smoked surface the curve B, seen to the left of the curve A. It will be perceived that this curve leaves the horizontal line at B,—that is, a little later than when the nerve was stimulated close to the muscle. It follows, therefore, that the distance on the horizontal line from A to B represents the time occupied by the transmission of the nervous impulse from B to A of the nerve. With suitable arrangements, the rate of movement of the glass plate can be measured by bringing into contact with it a marker on one of the prongs of a vibrating tuning-fork. The waves thus recorded enable the experimenter to measure with accuracy the rate of movement of the glass plate, and consequently the minute interval of time between A and B. In the diagram it will be observed that there are $2\frac{1}{2}$ waves between A and B; each represents $\frac{1}{10}$ th of a second; therefore the $\frac{1}{10}$ th of a second is the time represented by the distance A, B; or, in other words, the $\frac{1}{10}$ th of a second was occupied by the nerve-current in passing along the portion of nerve from B to A.

(2.) *Measurement of Velocity in Sensory Nerves.*—Suppose a sensory nerve to be excited in the hand; the theory of nervous conduction is that a change is propagated along the nerve to the brain, and that in the brain the molecular changes occur which result in a sensation. The individual having the sensation may feel it and make no sign by which any one else might be made aware that he has felt it, or the subject of the sensation might, by a muscular movement, such as the motion of an arm, let any one else see that he has felt the sensation. We have no means of knowing whether or not an individual has felt a sensation except by the individual making some kind of gesture or muscular movement. Now it is clear that, if we regard the brain as the seat of the changes resulting in sensation, the nearer any stimulated portion of skin is to the brain the sooner will the brain feel and respond to the stimulus. Thus, if the skin on the big toe of the right foot be stimulated, the effect of the stimulus passes to the brain and there calls forth a sensation, but if the stimulus be applied to the skin at the top of the thigh it is evident the effect has to pass along a shorter length of nerve and that the sensation in the brain will be aroused sooner. If we suppose that in each case the individual who is the subject of the experiment indicates the moment he feels the sensation, and that the instant the stimulus is applied successively to the skin on the toe and on the thigh is also accurately recorded, it is clear that he will signal the sensation of stimulation of the toe a little later than when he signals stimulation of the skin on the thigh, and that the difference will indicate the time required by the change in the nerve to pass along the length of nerve from the toe to the thigh. In the observation it is assumed that the time required for the changes in the brain resulting in sensation and volition, for the transmission along the motor nerve, and for the muscular contraction required to signal is the same in each experiment. Thus, supposing the total time between the moment of stimulating to the moment when the signal that the sensation has been felt and responded to is x , it is clear that this time is composed of a , the time required for the passage of the nerve-current in the first experiment from the toe to the brain, of b , the time required for the changes in the brain involved in sensation and volition, and of c , the time required for the transmission along the motor nerves and for the muscular contraction to move the signal,—that is, $x = a + b + c$. But, if the time between the moment of stimulating the thigh to the moment of signalling be shorter, and supposing that b and c are constant, then a varies according to the length of the nerve. Suppose the difference of time between the registration of stimulating at the toe and at the thigh to be y , then in the second experiment $x = a - y + b + c$,—that is, $y =$ the time occupied by the passage of the nerve-current from the toe to the thigh. This method has also been used to measure the time required for signalling a nervous impression in various circumstances, or what is usually called the "reaction period." The most convenient apparatus for the purpose is a chronograph made by König of Paris, the instrument being fully described in M'Kendrick's *Outlines of Physiology*, pp. 538-542.

The general result of measurements made by these methods is that the nerve-current travels slowly compared with the velocity of electricity or of light. In the motor nerves of the frog the velocity is about 87 feet (26 to 27 metres) per second, and in man and warm-blooded animals somewhat faster, 115 to 130 feet (35 to 40 metres) per second. The results as to velocity in sensory nerves vary from 50 to 100 metres per second. Cold retards, heat accelerates, the velocity. As already stated, the velocity is also retarded in a nerve in an anelectrotonic, and accelerated in a katelectrotonic state. The remarkable point is that the transmission of the nerve-current is slow, and that events appearing to our consciousness instantaneous require a considerable time for their occurrence. It may be laid down as a general truth that all kinds of nervous actions, even those considered as purely psychical, require time.

Heat-production by nerves. *Production of Heat by Nerves.*—It is extremely doubtful whether the production of heat by a nerve in action has been detected, although theoretically one would expect heat to be so produced. Schiff observed an increase of temperature on tetanization in the nerves of warm-blooded animals that had been artificially cooled; on the other hand, Helmholtz and Heidenhain's experiments yielded only negative results.

Electrical Phenomena of Nerve.—When a piece of nerve is properly brought into contact with the terminals of a sensitive galvanometer, a current flows through the galvanometer from the surface of the nerve to its transverse section (see fig. 4).

If metallic conductors, composed (say) of zinc, from the galvanometer were brought into connexion with a piece of nerve removed from an animal newly killed, little or no current would be obtained, and even if there were a current it might be due to contact of the metallic conductors with the living tissue exciting electrolytic decomposition. Hence it is necessary to have a fluid interposed between the metal and the animal tissue, say, for example, the zinc wire or plate forming the terminals of the galvanometer is immersed in a saturated solution of sulphate of zinc. But as sulphate of zinc solution would have the effect of irritating the living muscle it is necessary to have an inactive substance between the tissue and the sulphate of zinc solution. All these conditions are fulfilled by the non-polarizable electrodes of Du Bois-

Reymond, of which there are various forms. Two zinc troughs, mounted on insulating plates of vulcanite, have the inner surfaces carefully amalgamated. These are filled with a saturated solution of sulphate of zinc, and in each trough is placed a small cushion of clean blotting or filter paper, which quickly becomes permeated with the solution. Finally, a small plate of sculptor's clay, or kaolin, moistened with a half per cent. solution of common salt, or,

FIG. 4.—Diagram of apparatus of Du Bois-Reymond for experiments on electrical condition of muscle and nerve. *a*, zinc troughs, mounted on pieces of vulcanite *b*; *c*, paper pads; *d*, *e*, small pieces of moist clay; *f*, *f'*, binding screws for attaching terminals of galvanometer *g*. A small piece of paper connects *d* and *e*, and thus completes the galvanometer circuit. (Wundt.)

still better, with saliva, is laid on each paper pad. These clay pads are for guarding the tissue from the irritant action of the sulphate of zinc. Wires are carried from the troughs to the galvanometer, and a key is interposed in the circuit. The object of these careful arrangements is to secure that no current is formed by the apparatus itself. If now a small piece of nerve be so placed on the clay pads that the transverse section touches one pad and the longitudinal surface the other, and the key is opened, a current passes through the galvanometer, as indicated by the swing of the needle. Suppose that the needle is allowed to come to rest, the amount of deflexion of course indicating the strength of the current, and the nerve is now irritated so as to call forth its physiological activity, then the needle swings back towards zero. This backward swing is called the negative variation of the nerve-current. The electromotive force of the current obtainable from a frog's sciatic nerve is about '022 of a volt, and somewhat more from the sciatic nerve of a rabbit. This is somewhat less than the electromotive force of a frog's muscle, which varies from '035 to '075 of a volt. According to the views of Hermann, the negative variation-current is a true current indicating, and indeed preceding, the physiological activity of the nerve. He denies that the currents pre-exist in nerve or muscle, and states that the first current observed when the nerve is laid on the pads is simply due to the lower potential of the transverse section, caused by the rapid death of the nerve-substance. The nerve-current excited by a series of irritations, say feeble induction-currents, may be regarded as composed of a wave-like series of momentary currents, each of which is preceded by a negative variation-current. Thus the electrical phenomena of nerve are similar in kind to those manifested by living muscle.

Nutrition of Nerves.—Probably nerves are nourished by the Nutri-plasma reaching the axis-cylinder at the nodes of Ranvier; but it is not clear how it would appear from the researches of Waller that the nutrition of nerves, the nerve-fibre is influenced by the nerve-cell with which it is connected. The so-called "law of Waller" is well illustrated in the case of division of the roots of the spinal nerves. Each of these nerves has two roots,—a posterior, sensory, on which there is a ganglion; and an anterior, motor. If the anterior root be divided, in the course of a few days the end of the nerve cut off from the spinal cord is found to be undergoing degeneration, whilst the end attached to the cord is still normal. Again, if the posterior root be divided between the ganglion and the cord, the end remaining in connexion with the ganglion remains unaffected, whilst the other end undergoes degeneration. This degeneration, in the case of a motor nerve, affects the nerve to its very terminations. The axis-cylinder disintegrates into drops of fatty matter, and the medullated structure entirely disappears. It is well known that when a nerve is cut the ends may reunite so completely as to ensure a return of the normal function in from two to five weeks. According to Ranvier, the axis-cylinders in connexion with the central portion play an important part in this regeneration. They become larger, striated, and by and by form new axis-cylinders, which pass into the cicatricial tissue and come into contact with the other end of the divided nerve. This is a remarkable confirmation of the view of Waller that the nutritional activity of a nerve-fibre is in the direction of its physiological activity.

Nature of Nerve-currents.—The intrinsic nature of the change Nerve in a nerve-fibre effected by a stimulus is quite unknown; but it is currents. It is important to appreciate clearly the view that a nerve is both a receiver and a conductor of impressions. It can be stimulated in any part of its course, and from the stimulated point some kind of change is propagated along the nerve. This change is analogous to the passage of electricity along a conductor, or to the rapid passage onwards of a series of chemical decompositions, as when a long thin band of gun-cotton properly prepared is seen to slowly burn from end to end, or to the quick transmission of isomeric changes; but the analogy is not complete in any case. Whatever

the change may be, however, it does not appear to pass from one nerve-fibre to another running alongside of it. Each fibre conducts only its own impression, and there is nothing analogous to the inductive effect of one electrical conductor upon an adjacent one. Another question much debated is whether sensory and motor nerves act in the same way; or, in other words, is there any essential difference between them? There appears to be no difference in mode of action; the difference in the effect produced depends on the apparatus in which the nerve ends. Thus there may be contraction of a muscle if the nerve terminates in a muscle, change of the calibre of a blood-vessel if the nerve ends in that structure, secretion from a gland if the nerve is in connexion either with the vessel or the nerve-cells of a gland, an electrical discharge if the nerve ends in the electrical organ of a *Torpedo* or *Gymnotus*, and a feeling or sensation if the nerve-fibres go to a sentient brain. In all these instances the nature of the change in the nerve and the mode of its transmission are the same, and the results are different because the nerves terminate in different kinds of structure. It would appear from experimental evidence that, when a nerve-fibre is irritated, say about the middle of its length, a change is simultaneously propagated towards each end; but, as only one end is in connexion with an apparatus capable of responding, the effect at this end is the only one observed. Thus, if a motor nerve be irritated, there is muscular contraction, in consequence of the stimulus rousing the muscular substance into activity, probably through the agency of the end-plates; but there will be at the same time a backward wave along the nerve to the motor centres in the cord or brain. It is doubtful whether the nerve-energy becomes weaker or gathers intensity as it passes along a nerve; but the balance of evidence is in favour of the view that the so-called "avalanche theory" of Pfüger, according to which the energy gathers intensity as it passes along, is incorrect.

Nerves
classified.

Classification of Nerves.—Functionally, nerves may be classified into motor, sensory, vascular, secretory, and inhibitory. The original meaning attached to the term "motor" nerve was a nerve entirely composed of fibres by the excitation of which influences were conveyed to a muscle which caused the muscle to contract. As these influences passed outwards from a nerve-centre towards the periphery of the body they were also termed "efferent" nerves. On the other hand, nerves were found which, when stimulated, gave rise to sensations of pleasure or of pain, and these were called "sensory" nerves. Finally, it was shown that a third class of nerves were composed both of sensory and of motor fibres, and they were called "senso-motor" nerves. Sensory nerves were also subdivided into those of general and those of special sensibility. This was an artificial classification based on the fact that when a nerve of so-called special sensibility, such as the optic, was stimulated in any way the same kind of sensation followed. Thus stimulation of the optic nerve by cutting, pricking, pressure, or electricity is always followed by a luminous sensation. But the progress of research showed that when certain nerve-fibres were stimulated the result was not necessarily a muscular contraction: it might be contraction of a blood-vessel, modified secretion of a gland, or a diminution or arrest of some kind of nervous action. These facts demand another classification of nerves such as the following.

- | | |
|--|--|
| CENTRIFUGAL, OR EFFERENT, OR MOTOR, conveying influences outwards from a nerve-centre. | <ol style="list-style-type: none"> 1. Motor, sometimes termed <i>efferent</i>, to muscles, exciting contraction. 2. Secretory, to the cells of glands, causing secretion, possibly a particular kind of secretion. 3. Vascular, or <i>vaso-motor</i>, to the walls of blood-vessels, so as to cause contraction (<i>vaso-motor</i>) or dilatation (<i>vaso-dilators</i>, or <i>vaso-inhibitors</i>). 4. Inhibitory, so affecting other centres of nervous activity as to moderate or neutralize their action. 5. Electrical, so affecting a special organ as to call forth electrical discharges, as in electric fishes, <i>Torpedo</i>, <i>Gymnotus</i>, <i>Malapterurus</i>, &c. <ol style="list-style-type: none"> a. General, conveying to nerve-centres in brain influences which cause sensations of a vague character, scarcely perceptible to consciousness, and not permanent, as from lungs, heart, stomach, &c. b. Special, conveying to nerve-centres in brain influences which cause visual, auditory, gustatory, olfactory, or tactile sensations. |
| CENTRIPETAL, OR AFFERENT, OR SENSORY, conveying influences inwards towards a nerve-centre. | <ol style="list-style-type: none"> 1. Sensory, causing more or less acute sensations. 2. Afferent, or reflex, conveying to nerve-centres influences which usually cause no sensation, and which may or may not be followed by movements, secretions, changes in calibre of vessels, &c. |

In addition there are nerve-fibres connecting nerve-cells in the great centres, to which no special functions can be attributed.

2.—TERMINAL ORGANS.

Terminal organs. Although, as has been shown, a nerve may be stimulated in any part of its course, the stimulus is usually applied to a special structure adapted physiologically for the reception of the particular kind of stimulus. Such a special structure may be termed a

"terminal organ." For example, in the mechanism of vision (see EYE, vol. viii. p. 821 *sq.*) there are the retina or terminal organ, the optic nerve or conductor, and the brain or a portion of it, the recipient of the impression. The fibres of the optic nerve are not affected by light, but when they are mechanically or electrically irritated the result is a luminous sensation, because the action of the fibres of the optic nerve is to call forth in the brain the mechanism connected with luminous sensations. But light has a specific action on the retina, and in turn the activity of the retina stimulates the fibres of the optic nerve. The retina is therefore the terminal organ adapted for the reception of rays of light. In like manner, each sense has its appropriate terminal apparatus, and these are described under the headings of the various senses, EAR, EYE, SMELL, TASTE, TOUCH. To understand the true nature of nervous action it is necessary to be clear as to the functions of the terminal organs. They are liberating mechanisms. They do not transform the outer energy into the physiological energy, nervous action; but they call it into action. Thus light acting on the retina is not directly transformed into nervous energy, but it excites changes in the retina, which in turn produce activity of the optic nerve. The structure of each of these terminal organs need not be here described, but it may be stated that they all essentially consist of modified epithelium-cells, or what may be called "nerve-epithelium." In tracing their development throughout the animal kingdom it will be found that the simplest terminal organs are epithelium-cells on the surface of the body; but during evolutionary progress from lower to higher forms these cells become more and more modified and more and more protected by descending deeper into the structure of the animal, until we meet with the complicated organs of special sense in the higher animals. Another class of terminal organs is that comprehending the forms at the ends of motor nerves. Such are the end-plates found in muscle, and described in vol. i. pp. 861, 862. The different modes of nerve-termination may be here briefly classified.

Organ.	Terminal Organ.	Effect.
Skin (see TOUCH)	Tactile cells of Merkel, in the epidermis. Tactile corpuscles of Wagner and Meissner, in papillae of the skin. End-bulbs of Krause, in conjunctiva, penis, and clitoris. Pacinian bodies, attached to nerves of hand or foot, or in the mesentery. Corpuscles of Grandry, found in bills of birds. Network of fibres, as in cornea.	Touch, pressure, or temperature.
Ear (see vol. i. p. 894, and vol. vii. p. 591).	Hair-cells, supported by arches of Corti, and connected with the basilar membrane.	
Eye (see vol. i. pp. 886 and 888, and vol. viii. p. 816).	Rods and cones of retina.....	Vision.
Nose (see SMELL)	Rods and olfactory cells.....	Smell.
Tongue (see TASTE)	Taste-buds and gustatory cells.	Taste.
Muscles (vol. i. p. 862)	Motorial end-plates of Doyère, Kühne, Krause, Ranvier, &c.	Motion.
Glands	Nerve-endings in secreting cells.—Pfäuger and Knipfer.	Secretion.
Electric organs (see vol. xii. pp. 649, 650).	Laminae with free cilia-like processes.	Electric discharge.

3.—CENTRAL ORGANS.

A.—General Physiology of Central Organs.

General Structure.—The central organs consist of a special kind of cells called "nerve-cells," of nerve-fibres, both medullated and non-medullated, and of a variety of connective tissue, termed "neuroglia." On cutting into any central nervous organ, such as

FIG. 5.—Various forms of nerve-cells. a, multipolar, Shapes from grey matter of spinal cord; b, d, bipolar, from of nerve-ganglia on posterior roots of spinal nerves; c, g, unipolar, from cerebellum; e shows indications of a cell process coming off at lower end; f, union of three multipolar cells in spinal cord; g, union of three tripolar cells in grey matter of cerebral hemispheres.

The cells of the spinal ganglia are usually rounded; those of the sympathetic more angular; those of the spinal cord multipolar,—that is, having many processes or poles connected with them; those of the cerebrum triangular or pyramidal; and those of the cere-

bellum flask-shaped, having processes at each end. A nerve-cell shows a large clear nucleus and a small nucleolus, whilst the cell-substance is very granular. Some observers think they have traced into the substance of the cell a fibrillated structure from the axis-cylinder of the nerve-fibre ending in the pole or process; but this is doubtful, and the appearance may be accounted for by the action of the reagent employed and by the great difficulty of correctly interpreting optical appearances under very high powers. The neuroglia is a delicate interstitial connective substance having small connective-tissue corpuscles imbedded in it.

Chemical Constitution of Grey and White Matter.—This is still imperfectly known, and throws almost no light on the functions of the central organs. By various chemical processes the following substances have been obtained from nervous matter: cerebrin, lecithin, albumin, neurokeratin, cholesterolin and fats, creatin, xanthin, hypoxanthin, inosite, lactic acid, volatile fatty acids, salts, and water. The grey matter of the brain is distinguished chemically from the white chiefly by containing more water, albumin, lecithin, and lactic acid, and less cholesterolin, fat, and protagon (Hermann). Doubtless many of these substances are derived from the disintegration of a more complex chemical substance not yet isolated in a pure state from nervous matter. Petrowsky gives the composition of grey and white matter as follows.

	Grey matter.	White matter.
Water	81.6	68.4
Solids	18.4	31.6
The solids consist of—		
Albumins and gelatin	55.4	27.7
Lecithin	17.2	9.9
Cholesterolin and fats	18.7	51.9
Cerebrin	0.5	9.5
Substances soluble in ether	6.7	3.3
Salts	1.5	0.6

The salts found in nervous matter are similar to those in blood, and it would appear that phosphates, or rather combinations in which phosphorus exists, are the most prominent products of analysis. Thus about 40 per cent. of the salts consist of phosphates of soda and of potash—that is, the ash, on analysis, gives this result; but it must not be inferred that in nervous tissue phosphates of the alkalis exist to this amount, as there is every reason to think that phosphorous compounds, along with alkalis, exist in nervous matter, although not in the form usually called phosphates. The remarkably large amount of water, amounting to no less than from 70 to 80 per cent., indicates matter in a condition suitable for rapid molecular changes, on which, no doubt, the functions of the tissue depend.

Excitability of Grey Matter.—As grey matter contains both nerve-fibres and nerve-cells, and as these cannot be separated in any experiment, it is clear that no precise results can be obtained from any effort to distinguish the excitability of grey matter from that of white. The excitability of the grey matter must depend on blood-supply and on the rapid removal of waste-products. If the first be deficient either in quantity or quality, or if the second be not carried on so rapidly as to get rid of the waste-products as they are formed, the activity of the nerve-cells must suffer. The sudden deprivation of blood, as when the heart ceases to beat for even half a second, will cause unconsciousness; the mixture with the blood of a small quantity of bromide of potassium, or of alcohol, or of chloroform or other anæsthetic, or of morphia, will affect the activity of the brain. And it is well known that, when disease of the kidney, or such a disease as an acute fever, affects the body, matters may accumulate in the blood which so contaminate it as to make it unfit to carry on the vital changes on which activity of brain depends, and the result is delirium or unconsciousness. There is every reason to believe that the activity of nerve-cells is delicately attuned to surrounding conditions. A small excess per cent. of carbonic acid, or a small amount of what we call a poison, is sufficient to modify or arrest their action. The rhythmic action of various centres, such as those controlling the movements of respiration, is in favour of the view that the activity of such centres depends on delicate equipoises. If during expiration there is for the moment a deficiency of oxygen in the blood, or an accumulation of carbonic acid, the result will be an attempt at inspiration. This gets rid of the carbonic acid and introduces oxygen, and an expiration ensues. It is not pretended here to state what exactly happens, as these phenomena of respiration are still obscure, but they are brought forward with the view of showing that the actions of the rhythmic centres of respiration depend on the delicate balance established between the external conditions and those centres. If this be the case there is little doubt that a similar effect is produced on other centres by the nature of the blood supplied, and that the quality and quantity of the supply are important factors in the production of all conscious conditions.

General Phenomena manifested by Nervous Centres.—Before entering on a detailed description of the functions of the great centres such as spinal-cord and brain, it is well to take a survey of some of

the general phenomena manifested by such centres. These may be grouped under the heads of (1) reflex actions, (2) inhibitory actions, (3) accelerating actions, (4) vaso-motor actions, (5) secretory actions, (6) sensations, and (7) intellectual acts.

Reflex Actions.—Impressions made on sensory nerves are conveyed to nerve-centres, where they may or may not awaken consciousness. A sensation may be defined as the consciousness of an impression, and may or may not be followed by motion. Either motion may be voluntary, or it may be caused by direct stimulation of the motor nerve distributed to the muscles. The latter kind of action in the living body is not common. Usually motor nerves are acted on by the will or by emotional states; but it not unfrequently happens that physical stimuli occasion motion in an indirect manner, the impressions being carried along sensory nerves to a central organ, where changes are excited which result in a discharge of nervous energy along motor nerves to various muscles. Thus a frog in which the brain and medulla oblongata have been destroyed will draw up its limbs if the foot be pinched. Such actions, taking place without consciousness, are called "reflex actions," and the mechanism required for their performance may be thus described: (1) excitation of a sensory or afferent nerve, (2) excitation of an intermediate nervous or reflex centre, and (3) excitation of a motor or efferent nerve, which causes a muscular contraction. The diagram in fig. 6 shows the simplest mechanism; but it is rare to find the arrangements so simple, and the mechanism may become more complex (see fig. 7) either by the existence of a number of cells or groups of cells in the nerve-centre, or by the existence of numerous afferent or efferent nerves. The essence of a reflex action is the transmutation by means of the

FIG. 6.—Simple reflex action; 1, sensory surface; 2, muscle; a, sensory nerve; b, nerve-cell; c, motor nerve. The arrows indicate the direction in which the influence travels.

FIG. 7.—Double reflex action, or action in which two or more nerve-cells are involved; 1, 2, as in fig. 6; a, motor nerve; b, c, nerve cells.

irritable protoplasm of a nerve-cell of afferent into efferent impulses (Foster). The following is a brief summary of the leading facts relating to reflex action.

(a) The initial excitation may occur both in nerves of general sensibility and in those of the special senses; but certain nerves more easily excite reflex actions than others. Thus when light falls on the retina there is contraction of the pupil, the afferent nerve in this case being the optic (see vol. viii. p. 821 sq.).

(b) A reflex movement may occur whether we excite a sensory nerve at its commencement or at some point in its course, but in the latter case the action is less intense than in the former.

(c) Grey matter containing nerve-cells constitutes the chief portion of reflex centres, and groups of such reflex centres are frequently associated by internuncial fibres. The excitability is increased when these centres are severed from communication with psychical centres which preside over voluntary movements. Thus, after decapitation, reflex movements occur with greater intensity than in the injured animal; they are also more active during sleep. It is evident, therefore, that reflex actions may be restrained or hindered in their development by the action of higher centres. This is termed the "inhibition of reflex action."

(d) Reflex movements may occur in one muscle, or in many muscles or groups of muscles. One or more groups of muscles may be involved according to the strength of the stimulus applied to the sensory surface and the degree of excitability of the reflex centre at the time (see fig. 8). The facts are thus summarized by Pflüger. Unilateral action; if in a decapitated frog we excite the skin of the hind foot *p*, the excitation is transmitted from the centre *a* to the muscles 1 of the foot on the same side. Symmetrical action; if the excitation be more intense, it is transmitted to a centre on the

opposite side *b*, and contractions may occur in the muscles of the hind limbs on both sides 1, 2. Irradiation; if the excitation be still increased in intensity, it affects higher centres *c*, *d*, and there may be contraction of the fore-limbs 3, 4. General action; if the excitation be still further increased, it may pass to a still higher reflex centre *e*, and the result is general convulsions.

(c) Reflex centres may be so arranged in the body as to constitute a series in which those of the cerebrum govern or control others in the deeper ganglia of the brain, while these, in turn, have an influence over still lower centres in the spinal cord. This arrangement is termed the "superposition of reflexes" (see fig. 9).

(f) Stimulation of a sensory surface may simultaneously produce, by a reflex mechanism, movement, secretion, and consciousness. Thus a condiment in the mouth may cause involuntary twitchings of the muscles, secretion of saliva, and a sensation (see fig. 10).

(g) Certain substances, in particular strychnin, increase reflex excitability, so that the slightest external stimulation of the sensory nerves of the skin is sufficient to cause severe convulsions. On the other hand, bromide of potassium, hydrate of chloral, and atropin diminish reflex excitability.

(h) Individual stimuli only excite a reflex act when they are very powerful, but stimuli applied at frequent intervals act the more quickly and powerfully the more rapidly they succeed each other. To produce the reflex change in the centre, therefore, a summation or addition of centripetal excitations is required. When these reach a certain number the centre responds (Stirling).

(i) Reflex actions involve time. Thus the time between the stimulation and the movement can be measured, and, if we take into consideration the time occupied by the passage of the nerve-current along the nerves involved, and the latent period of muscular contraction, and subtract this from the total time, the remainder will represent the time occupied by the changes in the centre or the reflex-time. This has been found to be from '0555 to '0471 of a second. It is lengthened by cold and shortened by increasing the strength of the stimulus and by strychnia.

(k) In compound reflex acts the initial excitation may occur in psychical centres, as when the recollection of an odour causes nausea, or when a feeling of ennui is followed by a yawn.

(l) Some reflex movements are the result of inherited peculiarities of structure, as those made by a new-born child when it seizes the breast. Other reflex movements are acquired during life. Such are at first voluntary, but they become automatic by repetition.

Examples of reflex action.

The following are some of the more common examples of reflex movements. Motions of the muscles in any part of the limbs or trunk under the influence of sensory impressions on the skin, such as tickling, pricking, &c.; shuddering from cold, shuddering caused by grating noises, &c.; contraction of the pupil under the influence of light on the retina; winking from irritation of the sensory nerves of the conjunctiva; sneezing, from irritation of the Schneiderian membrane, or by a glaring light on the eye; spasm of the glottis and coughing, from irritation of the larynx or trachea; laughing, caused by tickling the skin; the first respiration of the child at birth, from the impression of cold upon the nerves of the skin, and especially those of the chest; respiratory movements in the adult, from the impression caused by the afferent nerves of the lungs (sympathetic or vagus), by the presence of carbonic acid in the air cells and passages, or in those of the general system,—also, occasional modifications of the respiratory movements from impressions of cold, &c., on the surface of the body; sucking in infancy; deglutition or swallowing, with all the complicated movements then occurring in the tongue, fauces, larynx,

and gullet; vomiting, caused by irritation in stomach, or in fauces, or following nausea; forced contractions of the sphincter muscles of the anus, urinary bladder, and vagina, under local irritation; erection and emission under the influence of irritation of the nerves of the penis and other parts in the vicinity; rhythmic movements of lymphatic hearts in reptiles; rhythmic movements of the heart by the action of cardiac ganglia; peristaltic motions of the stomach and alimentary canal, in digestion and in defecation, &c., under the influence of impressions conveyed to the ganglia by the splanchnic and intestinal nerves; action of the bladder in expelling urine; expulsive action of the uterus in parturition; contractions and dilatations of the blood-vessels under the influence of the vaso-motor system of nerves; many obscure and complex morbid actions, such as palpitations of the heart, cramps in the limbs caused by irritation in the stomach or intestinal canal, fainting from concussion or from peculiar odours, dilatation of the pupil and grinding of the teeth from the irritation of worms, and the convulsive seizure sometimes occurring during teething.

Inhibitory and Accelerating Actions.—As we have seen, stimulation of a nerve may cause a sensation, a reflex action, or the direct motor contraction of a muscle; but in some instances when the nerve and is stimulated movements may be arrested. This occurs where accelerating and apparently spontaneous or automatic actions are exerting restrained or inhibited by the activity of certain nerves. The most actions,

striking instance of inhibition is offered by the heart. The subject will be readily understood with the aid of fig. 11, which illustrates the innervation of the heart and blood-vessels and especially the inhibition and action of the depressor nerve.

It is well known that the heart of a warm-blooded animal ceases to beat almost immediately after removal from the body, but the heart of a cold-blooded animal, such as the frog, will beat for hours or even days, especially if it be supplied with defibrinated blood. The rhythmic beat depends to some extent on the existence in the heart of ganglia or small nerve-centres (fig. 11, I, A, R). It is quite true, however, that rhythm may go on in a portion of the heart containing no ganglionic structure. Now the heart receives nerves from two sources, from the vagus or pneumogastric nerve and from fibres derived from the spinal cord through the sympathetic. If the vagus be cut and the lower end stimulated by feeble induction-shocks, the heart beats more slowly, and will probably be brought to a stand-still in a dilated condition. A strong stimulation of the vagus will invariably arrest the action of the heart, and the organ will be

found dilated, or, as it is said, in a state of diastole. On removal of the stimulus the heart will soon resume its beats. It is clear that the vagus cannot be regarded as the motor nerve of the heart, because, if so, stimulation would have arrested the action of the heart in a state of contraction or systole. The question, then, is whether the fibres of the vagus possessing this remarkable power of inhibiting or restraining the action of the heart terminate in the muscular fibres, or in some intermediate structures, such as ganglia. The influence of various poisons has shed light on this question. A minute dose of atropin injected into the blood paralyses this inhibitory action. After such a dose stimulation of the vagus is followed by no effect, and the heart beats as usual.

"Again, in slight urari poisoning the inhibitory action of the vagus is still present; in the profounder stages it disappears, but even then inhibition may be obtained by applying the electrodes to the sinus. In order to explain this result, it has been supposed that what we may call the inhibitory fibres of the vagus terminate in an inhibitory mechanism (probably ganglionic in nature) seated in the heart itself, and that the urari, while in large doses it may paralyse the terminal fibres of the vagus, leaves this inhibitory mechanism intact and capable of being thrown into activity by a stimulus applied directly to the sinus. After atropin has been given inhibition cannot be brought about by stimulation either of the vagus fibres or of the sinus, or indeed of any part of the heart. Hence it is inferred that atropin, unlike urari, paralyses this intrinsic inhibitory mechanism. After the application of muscarin or pilocarpin the heart stops beating, and remains in diastole in perfect stand-still. Its appearance is then exactly that of a heart inhibited by profound and lasting vagus stimulation. This effect is not hindered by urari. The application, however, of a small dose of atropin at once restores the beat. These facts are interpreted as meaning that muscarin (or pilocarpin) stimulates or excites the inhibitory apparatus spoken of above, which atropin paralyses or places *hors de combat*" (Foster, *Text-Book of Physiology*, 4th ed., p. 186).

Thus physiologists are satisfied that, when the vagus is stimulated, currents of nerve-energy pass along its fibres to some of the intrinsic ganglia of the heart and inhibit or restrain these, so that the heart beats more slowly or is arrested altogether. But the centres in the heart may also be stimulated. After division of both vagi in a mammal, say a rabbit, the heart's beat may be quickened or accelerated by stimulation of the cervical spinal cord. Fibres having this power of accelerating the action of the heart have been traced from

FIG. 9.—Diagram illustrating the superposition of reflexes. *m*, *m*, muscles; 1, 1, series of reflex centres on one side, under the control of 2, 2, which are again governed by 3. There is a corresponding series, 1', 1'; 2', 2'; 3' on the other side. Both sides are presided over by 4. Thus a stimulus reaching 4 might excite the activity of all the muscles *m*, *m*; if it reached 3, only one half of the muscles; if it reached 2, to the left, only three of the muscles; and, finally, if it affected 1, to the left, only one muscle *m*.

FIG. 10.—Diagram illustrating a complex reflex mechanism. The arrows indicate direction of currents. 1, sensory surface; 2, muscle; 3, gland; 4, sensory nerve; 5, reflex centre, connected with another reflex centre *d* by internuncial fibre *e*; 6, motor or efferent nerve; 7, secretory nerve passing to gland 3. From the other side of *d* is seen a fibre passing to the brain, and there exciting changes which result in a sensation.

the cervical spinal cord through the last cervical and first thoracic ganglia of the sympathetic. Stimulation of these *accelerator* nerves causes a quickening of the heart's beat, in which, however, "what is gained in rate is lost in force" (Foster). They are referred to here as showing another kind of nervous action, quite different from inhibition. Thus any nerve-centre concerned in reflex movements may have, by impulses reaching it from the periphery, its action inhibited or restrained or accelerated.

Nerves
and
blood-
vessels.

Influence of Nerves on Blood-Vessels.—If the sympathetic nerve be divided in the neck, there is a dilatation of the vessels and an increase of temperature on the same side; but irritation by weak induction-currents of the cephalic end will cause the vessels to contract and the temperature to fall. In the sympathetic, therefore, there are nerve-fibres which influence the contractile coats of the blood-vessels. These fibres, called "vaso-motor," originate from a vaso-motor centre in the medulla oblongata between the point of the calamus scriptorius and the lower border of the corpora quadrigemina, in the floor of the fourth ventricle. From this chief vaso-motor centre nervous influences emanate which tend to keep the smaller vessels in a more or less contracted condition. If it be injured, paralysed, or destroyed there is at once great dilatation of the vessels, more especially those in the abdominal cavity, and the blood collects in these dilated vessels. This of course diminishes the arterial pressure in the larger vessels. Consequently, by observations on blood-pressure, it has been found possible to study the conditions of vaso-motor action. By connecting a kymograph (a recording manometer) with a large vessel, say the carotid, observing for a time the mean blood-pressure, and afterwards injuring the supposed vaso-motor centre, Ludwig and his pupil Owsjannikoff at once observed an enormous fall of blood-pressure, to be explained by the paralysis of the smaller and a consequent emptying of the larger vessels.

The vaso-motor centre may be influenced—that is, inhibited, or possibly strengthened—by impulses coming from the periphery. Such impulses may be sent to the centre along any sensory nerve, but in 1866 Cyon and Ludwig discovered a nerve which apparently exercises this function to a remarkable extent. In the rabbit it originates by two roots from the superior laryngeal and from the vagus. Stimulation of the distal end of this nerve produces no effect, but stimulation of the cephalic end causes at once a great fall of blood-pressure in the arterial system and a diminution in the frequency of the pulse. As this nerve, therefore, inhibits, restrains, or depresses the activity of the vaso-motor centre it has received the name of the "depressor nerve of Cyon and Ludwig." It appears to influence chiefly the vaso-motor arrangements of the abdomen and lower extremities. Thus, after section of the splanchnics, which control the vessels of the abdominal viscera, it is said that excitation of the depressor does not produce nearly the same diminution of pressure in the carotid vessels. By the influence of the depressor a balance is kept up between the central and the peripheral circulations. Imagine the heart to be pumping blood through the vessels. If from some cause the smaller vessels become constricted so as to offer greater resistance to the passage of the blood, the arterial pressure in the larger vessels is increased, and the heart has more work to do to overcome this resistance. When the resistance reached a certain amount the heart would be in danger of exhaustion in endeavouring to overcome it. But by the depressor this danger is removed, as an influence may pass from the heart along the fibres of the depressor to the vaso-motor centre, the effect of which is to inhibit the activity of this centre, and thus allow the smaller vessels to dilate. When this occurs, either locally, as in the abdominal region, or generally, the result is a depletion of the larger vessels, a consequent fall of pressure in them, and therefore less resistance to the efforts of the heart. Thus it would appear that in the heart itself there is an arrangement by which, to a certain extent, it governs its own work, and there is an adjustment between the activity of the heart and distribution of blood throughout the body (see fig. 11).

The vaso-motor nerves causing contraction of vessels have been called "vaso-constrictors"; but there are other nerve-fibres possessing the property of causing a dilatation instead of a contraction. These have been called "vaso-dilators." Excitation of the chorda tympani nerve, for example, causes the vessels of the sub-maxillary gland to dilate (see vol. xvii. p. 672). Erection, as it occurs in the penis, has long been known to depend on dilatation of vessels and consequent increased afflux of blood. Stimulation of the nerves of the sacral plexus may cause erection. But how do such nerve-fibres act? It cannot be that they directly cause relaxation of the muscular fibres in the walls of the vessels. These contain layers of involuntary muscular fibres in the transverse and longitudinal directions, and it is difficult to understand how any contraction of fibres in either of these directions could possibly cause dilatation of the vessel. Probably the effect is brought about by the action of some kind of inhibitory mechanism. Ganglia abound in the walls of the vessels. From these, fibres pass to and from the muscular elements of the vessel. Such ganglia or local reflex centres may be supposed to be under the influence of two sets of nerve-fibres: (1) accelerating or strengthening, corresponding to the accelerating fibres that influence the heart; and (2) inhibitory, like the fibres of the vagus distributed to the heart, having the power of restraining the action of the local ganglia. According to this view, the fibres in the chorda which cause dilatation of the vessels of the sub-maxillary gland on stimulation are vaso-inhibitory nerves.

Nerves
and
glands.

Influence of Nerves on Glands.—This has already been described under NUTRITION (vol. xvii. p. 672), but the facts may be here briefly summarized. A secreting gland is supplied with three sets of nerve-fibres,—vaso-constrictor, vaso-dilator or vaso-inhibitory, and secretory. The first two regulate the distribution of blood in

the gland, whilst the third set directly affects the activity of the secreting cells. According to Heidenhain, in addition to the vascular nerves supplying a gland there are secretory and trophic nerves. "Stimulation of secretory fibres leads to an increased flow of water, stimulation of the trophic to an increased secretion of specific substances and to an increased production of protoplasm" (Gamgee). The vaso-constrictor fibres of a gland are derived from the sympathetic, and the vaso-dilator and secretory from the cerebro-spinal system.

Classification of Nerve-Centres.—Although these are usually Nerve-classified anatomically, according to the organ in which they are centres situated, they may also be arranged according to their functions, as classifies follows:—(1) *receptive* centres, to which influences arrive which fied, may excite sensations (in grey matter of brain), or some kind of activity not associated with consciousness (reflex centres of the cord and of the brain); (2) *psychical* centres, connected with sensation in the sense of conscious perception, emotion, volition, and intellectual acts (in the grey matter of the brain); (3) *discharging* centres, whence emanate influences which, according to structures at the other ends of the nerves connected with them, may cause movements, secretions, or changes in the calibre of vessels (in brain and spinal cord); (4) *inhibitory* centres, which inhibit, restrain, or arrest the actions of other centres.

B.—Special Physiology of Central Organs.

General Physiological Anatomy.—The central organs of the nervous system consist of ganglia or of what is called a "cerebro-spinal axis." The anatomy of the latter is described under ANATOMY, and some account of the gangliated cords in invertebrates and of the rudimentary nervous systems of the lower forms of vertebrates will be found under the articles CRUSTACEA, INSECTS, AMPHIBIA, BIRDS, ICHTHYOLOGY, &c. But, as one of the most effective ways of obtaining an intelligent conception of the complicated nervous system of man and of the higher animals is to trace its various forms in the scale of animal existence, and to observe the close correspondence between complexity of structure and complexity of function, a short introductory review of its comparative anatomy, from the physiological side, will here be given. In the first place, we find that the different forms of nervous systems may be divided into (a) those consisting of ganglia or chains of ganglia, as found throughout the invertebrates, and (b) those having a great axis of nervous matter forming a brain and spinal cord, the cerebro-spinal axis, as seen in vertebrates.

Comparative View of Nervous System of Invertebrates.—In the Nervous simplest forms of animals the protoplasmic cell is the seat of system sensation and of motion; but as the contractile or muscular of invertebrates become more marked sensation is relegated to the cells of the ectoderm, or outer layer of the body. As portions of this sensory layer become of higher value to the organism, their protection is accomplished by some of the sensory cells sinking into the body of the organism so as to be covered by less important structures. The portions, originally of the surface, thus differentiated and protected become ganglia, and processes pass from them on the one hand to cells in the periphery, so that they may still be influenced by external energies, and on the other to the contractile parts of the organism by which movements are accomplished. Still higher in the scale of life, the ganglia are connected by internuncial fibres, and the plan of the primitive nervous system bears a relation to the general type of structure of the animal. Thus in radiate animals the gangliated cords show a radiated arrangement, and when the animal form is bilateral and symmetrical the nervous arrangements are on the same type. It is also to be noted that the ganglion specially connected with the rudimentary organs of sense attains a size and importance proportionate to the development of the sense-organs. The nerves of the sense-organs are chiefly connected with the supra-oesophageal ganglion, which thus may be looked on as a rudimentary brain. When the body of the animal becomes more complicated by the development of similar segments (or metameres), we find that by a reduplication, as it were, of the subesophageal ganglion a ventral chain of ganglia is formed, a pair of ganglia for each segment, the individual ganglia being connected by longitudinal commissures. Such an arrangement is seen in the ringed worms and in arthropods. The next step is a fusion of ganglia into masses, according to the size and importance of the part of the body to be innervated (see vol. vi. p. 636, figs. 7 and 9).

No trace of a nervous system can be detected in *Protozoa*. The Scyphomedusoid forms of *Hydrozoa* show nerve-fibres and ganglion-cells (Schäfer) in the sub-umbrella and around the tentaculo-cysts (see vol. xii. p. 552, fig. 15), and in the Hydromedusoid forms the nerve-ganglion cells form a ring round the margin of the disk. In some of the *Actinozoa* (anemones, &c.) fusiform ganglionic cells united by nerve-fibres are said to exist (F. M. Duncan). In all the worms (*Vermes*) the most important central organs of the nervous system are placed in the anterior part of the body near the beginning of the alimentary canal. If they have a distinct head the nervous organ is in it and supplies branches to the sense-organs. From thence nerve-trunks radiate to the periphery of the body, often in the form of two longitudinal trunks on the ventral surface. Frequently there is a nervous ring round the oesophagus. Nerve-organs have been found in all the *Platyhelminthes*, *Rotatoria*, and *Bryozoa*. The *Nemathelminthes* show a further advance. The central organ is placed on the oesophagus, surrounding it as a ring, from which nerves radiate forwards and

backwards. Often six strands of nerve run forwards, whilst a dorsal and a ventral trunk pass backwards. The size of these trunks depends on the length of the body. The cephalic ganglion is bilateral and is largely developed. In the *Hirudinaria* and *Annelida* the cerebral ganglia are connected by commissures with a ventral cord, which, in turn, shows individual ganglia connected by commissures. Each ganglion consists of two equal portions with a transverse commissure, and in the higher forms they are so close as to form almost a single cord. It is also evident that the cerebral ganglia are composed of several ganglia fused together, and acquire functional importance as the sense-organs are more highly developed. In the *Echinodermata* the nervous system consists of a number of trunks placed ventrally and having a radial arrangement. Each of these trunks corresponds to the ventral ganglionic chain of the *Annelata*. In *Asterida* (star-fishes) each radial nerve consists of two bands thickened in the middle, and at the end there is a swelling connected with an optical apparatus placed there. In the *Echinus* (sea-urchin) the nervous ring lies above the floor of the oral cavity, between the oesophagus and the lips of the ossicles of the masticatory apparatus. From this ring lateral branches issue which accompany the branches of the ambulacral vessels. In *Holothuroida* (sea-cucumbers) the nervous ring lies in front and near the mouth, and is thicker than the five nerves which it gives off, thus differing from the *Asteroida* and *Echinoida*. The nervous system of the *Arthropoda* resembles that of the *Annelida*. There is a large ganglion above the oesophagus, the cerebral ganglion, united to a ventral ganglion by two commissures so as to form a nervous ring. From the ventral ganglion a series of ganglia united by commissures extends along the ventral surface of the body. The increased size of the cerebrum is the most striking characteristic, and no doubt bears a relation to the higher degree of development of the sense-organs, more especially those of sight. In some *Crustacea* the optic nerves arise from distinct lobes. As pointed out by Gegenbauer, when the optic organs are reduced or lost the cerebrum becomes so small as to be represented by nothing but a commissure. In the individuals having a large portion of the body composed of similar metameres the ganglia are regular in size, appearing in pairs. On the other hand, in the *Thoracostraca* (crabs, &c.) the anterior ganglionic masses are fused into larger masses so as to correspond to the confluence of the anterior metameres into a cephalo-thorax. In the abdominal portion of the body, where the metameres are small, distinct, and more or less regular, the ganglia are also distinct and in pairs. In the *Protracheata* (*Peripatus*) the nervous system is simpler, and consists of the oesophageal collar with a double ventral cord having no ganglia or swellings on it, although nerve-cells are distributed through it. In the *Myriapoda* there is a well-marked ventral cord, with ganglia corresponding to the metameres. In the *Arachnida* the ventral ganglia are often reduced in number and fused. They are characterized by the close connection between the cerebral ganglia and the ventral cord, owing to the extreme shortness of the commissures (Gegenbauer). In the *Scorpions* the nervous system is richly segmented, and remarkable for the large size of the ganglion giving off the pedal nerves. The *Spiders* have a single large ganglion in the cephalo-thorax, no doubt consisting of several ganglia. In the *Acarina* (mites) the cerebral ganglion is extremely small, and the other ganglia are fused so as to form one single mass, giving off nerves all round. These minute animals show a remarkable degree of concentration of the nervous system. (See fig. 12) the ventral cord traverses the whole length of the body, the ganglia being at equal distances, and all united by commissures. This condition is well seen in the larval condition, and is like the permanent state of the *Myriapoda*. When the insect passes into the adult condition changes occur, consisting essentially of the fusion of ganglia and a shortening of the commissures. The cerebral ganglion is composed primitively of three pairs, and in most cases does not unite with the rest of the ventral cord. It shows hemispheres and a complicated structure. The first ganglion of the ventral cord supplies the organs of the mouth; the three succeeding send nerves to the appendages, feet, and wings; the remaining ganglia are small, except the last, which supplies the generative organs. There is great variety among the *Insecta* in the number of ganglia in the ventral cord, but coalescence always indicates a higher type of structure. The nervous system of the *Brachiopoda* is formed of masses of ganglia near the oesophagus. From these nerve-fibres pass to various parts of the body. There is an oesophageal ring, but the superior ganglionic mass, which lies above the commencement of the oesophagus—the supra-oesophageal or cerebral ganglion—and a ventral mass which is connected with the other by commissures, and forms the inferior or pedal ganglia. They are both paired. The cerebral ganglion is connected with the sense-organs. Both the cerebral and the pedal ganglionic masses really consist of ganglia fused together. This is well shown in some of the lower forms, in which the pedal ganglia are divided, and form an arrangement like the ventral cord of the *Annelata*. The remarkable feature in the nervous system of *Mollusca* is the great development of the visceral ganglia and nerves supplying the heart, branchial apparatus, and generative organs (see vol. xvi. p. 643, figs. 17, 18; p. 644, figs. 20, 21, 22; p. 647, figs. 34, 35; p. 648, fig. 36). In the *Lamellibranchia* the cerebral ganglia are very small, owing to the absence of a head and its sense-organs. In some forms they are placed so much to the side as to be united by a long commissure. There are also two pedal ganglia, of a size proportional to the degree of development of the foot. The visceral ganglionic mass is often the largest. It lies behind the posterior adductor muscle, and is united by long commissures to the cerebral ganglion (vol. xvi. p. 698, fig. 144). The nervous system of the *Gastropoda* is remarkable for the large size of the cerebral ganglia. In the *Pteropoda* the cerebral ganglia either retain their lateral position or approach the pedal ganglia, with which the visceral ganglia are also fused. The three ganglionic masses, cerebral, pedal, and visceral, are also represented in the *Cephalopoda*, but they are more approximated by the shortening of the commissures. The ganglionic masses consequently are of great size, and they are more differentiated than any other ganglia in invertebrates. It is possible to distinguish an outer grey layer, formed of ganglionic cells, surrounding a white layer, composed of fibres (vol. xvi. p. 679, figs. 113, 114, 115). Lastly, in *Tunicata* the nervous system is dorsal, instead of ventral, as in other invertebrates. It is developed from the ectoderm, or outermost layer of the embryo, by an infolding so as to form at first a groove and afterwards a tube. In the *Ascidian* larvae this nervous tube reaches throughout the length of the tail, and we have thus the remarkable condition of a dorsal-median nerve-cord, analogous to the cerebro-spinal system of vertebrates. Further, embryologists are of opinion that this rudimentary nervous system is the true central organ, although the greater portion of it

disappears by the atrophy of the tail in the passage from the larval to the adult state. (Gegenbauer.)

Comparative View of Nervous System of Vertebrates.—To understand the structure of the complicated central nervous system of vertebrates, and to appreciate the physiological importance of its various parts, it is necessary to trace its development in the embryo, and to note the various forms it presents from the lowest to the highest vertebrates. A consideration of the embryological and morphological aspects of the subject clears up many difficult problems which a study of the human nervous system, by far the most complicated physiological system in the body, fails to do, and in particular it gives an intelligent conception of its architecture, as seen both in simple and complex forms. The cerebro-spinal axis begins in the embryo as a tube of nervous matter produced by an infolding of the epiblast, or outermost embryonic layer. The tube widens at its anterior end, and, by constrictions in its wall, three primary cerebral vesicles are formed, which afterwards become the anterior, middle, and posterior parts of the brain. In the fully-developed condition the cavity of the tube remains as the central canal of the spinal cord and the ventricles of the brain, whilst the various parts of the brain and cord are formed by thickenings in its walls. The three cerebral vesicles have been called the fore-brain, the mid-brain, and the hind-brain. A protrusion from the anterior cerebral vesicle, at first single, but afterwards divided by a median cleft, becomes the rudiment of the cerebral hemispheres (*prosencephala*), the cavity remaining in the adult condition as the lateral ventricle on each side. From each cerebral vesicle another hollow process protrudes which constitutes the olfactory lobe (*rhinencephalon*). What remains of the cavity of the first vesicle becomes the third ventricle (*thalamencephalon*). In the outer and under walls of the *prosencephala* a thickening is formed which becomes the *corpora striata*, two large bodies in the floor of the lateral ventricles of the adult brain, whilst the roof is modified into the substance of the cerebral hemispheres. Immediately behind the *corpora striata*, and in the floor of the thalamencephalon, two similar thickenings occur which become the *optic thalami*, a thin layer between the two constituting the *tentorium semicirculare*, and the Y-shaped canal passing from the cavity between the thalami to the cavities in the cerebral hemispheres (lateral ventricles) is the *foramen of Monro*. The floor of the third ventricle is produced into a conical process, the *infundibulum*, at the blind end of which is the pituitary body, or *hypophysis cerebri*. The roof of this ventricle is very thin, and in connexion with it is developed the pineal gland, or *epiphysis cerebri*. Transverse fibres pass from the one corpus striatum to the others, constituting the *white commissure*, whilst the two optic thalami are connected by two *grey commissures*. In mammals the two cerebral hemispheres are connected by a large and important set of commissural fibres, forming the *corpus callosum*. In addition there are certain sets of longitudinal commissural fibres. Thus two sets of fibres arise from the floor of the third ventricle, arch upwards, and form the *anterior pillars of the fornix*. These are continued over the roof of the third ventricle and run backwards, constituting the *body of the fornix*. Behind this the bands diverge so as to form the *posterior pillars of the fornix*. In the higher vertebrates the upper lip of the foramen of Monro thickens, and becomes converted into a bundle of longitudinal fibres, which is continuous anteriorly with the anterior pillars of the fornix. These are continued back between the inner boundary of the cerebral hemisphere and the margin of the *corpora striata* and optic thalami, and project into the lateral ventricle, forming the *hippocampus major*. As in highly-formed brains the corpus callosum passes across considerably above the level of the fornix, a portion of the inner wall of the hemisphere on each side and a space between are intercepted. The two inner walls constitute the *septum lucidum*, and the space the cavity of

the fifth ventricle. By a thickening of the floor of the middle cerebral vesicle (*mesencephalon*) two large bundles of longitudinal fibres, the *crura cerebri*, are formed, whilst its roof is modified into the optic lobes, *corpora bigemina* or *corpora quadrigemina*. The cavity, reduced to a mere tube, is the *iter a tertio ad quartum ventriculum*, or the *aqueduct of Sylvius*. The third cerebral vesicle, *myelencephalon*, undergoes less modification than the others. The upper wall is exceedingly thin before the cerebellum so as to form a lamina, the *valve of Vieussens*, whilst the part behind is covered only by membrane, and opens into the posterior subarachnoid space. The *cerebellum* makes its appearance as a thin medullary lamina, forming an arch behind the *corpora quadrigemina* across the wide primitive medullary tube. The portion forming cerebellum, *pons Varolii*, and the anterior part of the fourth ventricle is termed the *epencephalon*, whilst the remaining portion, forming the *medulla oblongata* and fourth ventricle, is the *metencephalon*. These facts are briefly summarized as follows (Quain, vol. ii. p. 828).

1. Anterior cerebral vesicle.	a. Prosencephalon —Fore-brain.	Cerebral hemispheres, corpora striata, corpus callosum, fornix, lateral ventricles, olfactory bulb (rhinencephalon).
2. Middle cerebral vesicle.	b. Thalamencephalon —Inter-brain.	Optic thalami, pineal gland, pituitary body, third ventricle, optic nerve (primarily).
3. Posterior primary vesicle.	c. Mesencephalon —Mid-brain.	Corpora quadrigemina, crura cerebri, aqueduct of Sylvius, optic nerve (secondarily).
	d. Epencephalon —Hind-brain.	Cerebellum, pons Varolii, anterior part of the fourth ventricle.
	e. Metencephalon —After-brain.	Medulla oblongata, fourth ventricle, auditory nerve.

The general architecture of the brain considered in this way will be understood by the diagram in fig. 15, whilst details as to the

Fig. 15.—Diagrammatic longitudinal and vertical section of a vertebrate brain. The *lamina terminalis* is represented by the strong black line between FM and 3. Mb, mid-brain, what lies in front of this being the fore-brain, and what lies behind the hind-brain; Olf, the olfactory lobes; Hmp, the hemispheres; ThE, the thalamencephalon; Pn, the pineal gland; Py, the pituitary body; FM, the foramen of Monro; CS, the corpus striatum; Th, the optic thalamus; CQ, the corpora quadrigemina; Cb, the crura cerebri; Cb, the cerebellum; PV, the pons Varolii; MO, the medulla oblongata; I, olfactorii; II, optici; III, point of exit from the brain of the motor nerves; IV, of the parietal; V, of the abducentes; VI-XII, origins of the other cerebral nerves; 1, olfactory ventricle; 2, lateral ventricle; 3, third ventricle; 4, fourth ventricle. (Huxley.)

exact anatomy of the human brain will be found under ANATOMY (vol. i. p. 869 sq.).

The complex structure of the brain in the higher animals arises to a large extent from the great development of the cerebral hemispheres. At a very early period these grow forward and project more and more beyond the region of the first primary vesicle, which, as has been noticed, never advances farther forward than the pituitary fossa (*lamina terminalis*); in expanding upwards they take the place previously occupied by the mid-brain, and fill the most prominent part of the head; and by a downward and lateral enlargement

Fig. 16.—Surface of fetal brain at six months (from R. Wagner). This figure is intended to show the commencement of formation of the principal fissures and convolutions. A, from above; B, from left side. F, frontal lobe; P, parietal; O, occipital; T, temporal; a, a, slight appearance of several frontal convolutions; s, Sylvian fissure; s, its anterior division; within C, central lobe or convolutions of island of Reil; r, fissure of Rolando; p, parieto-occipital fissure. (Quain.)

they form the temporal lobes. Thus frontal, parietal, and temporal lobes come to be distinguishable, and somewhat later, by a farther increase posteriorly, the hindmost lobes constitute the

occipital lobes, and the cerebrum at last covers completely all the lower parts of the brain. The hemispheres, therefore, which are small in the early embryo of all animals, and in adult fishes permanently, attain so large a size in man and in the higher animals as to conceal all the other parts. Whilst this general development is going on the layer of grey matter on the surface of the hemispheres increases to such an extent as to throw the surface into folds or convolutions. The upper surface of the hemispheres is at first smooth (see fig. 16). The first appearance of division into lobes is that of a blunt notch between the frontal and temporal parts below, in what afterwards becomes the Sylvian fissure. In the fourth and fifth months there appear the vertical fissure, separating the parietal and occipital lobes, and the transverse fissure, called the fissure of Rolando, which divides the frontal and parietal lobes superiorly, and which is peculiarly characteristic of the cerebral type of man and of the apes (Allen Thomson). Then the convolutions appear from the formation of secondary grooves or sulci, for even at birth they are not fully perfected; and by the deepening of the grooves and the formation of subordinate ones the process goes on during the first years of infancy. For the convolutions see vol. i. p. 873; also PHRENOLOGY, vol. xviii. p. 847.

The evolution of the brain throughout the animal kingdom shows developed a graduated series of increasing complication proceeding out of the ment of same fundamental type; so that the forms of brain found permanently in fishes, amphibians, reptiles, birds, and in the lower mammalians are repetitions of those shown in the stages of the embryonic series. development of the brain of one of the higher animals.

In the whole class of fishes the brain retains throughout life more or less of the elementary form,—that is, it consists of a series of

Fig. 17.—Typical forms of brains of lower vertebrates. A. Brain of tortoise (*Testudo*). 1, olfactory; 2, cerebral lobes; 3, corpora striata; 4, optic lobes; 5, medulla. Part of the surface of the cerebral lobes has been removed to show the cavities in the interior, termed "the ventricles." Immediately behind 4, the optic lobes, is the imperfectly developed cerebellum. B. Brain of common frog (*Rana*). a, olfactory; b, cerebral lobes covering corpora striata; c, corpora quadrigemina, or optic lobes; d, cerebellum (rudimentary); e, back of medulla, showing fossa. C. Brain of trout (*Trigla*). 1, olfactory; 2, cerebral lobes; 3, optic lobes; 4, cerebellum.

considerably larger. In osseous fishes (*Teleostei*) the thalamencephalon is so fused with the mesencephalon as to make the homology of the parts difficult to trace, but both cerebellum and cerebrum are still small relatively to the rest of the brain. The most important part of the brain of a fish is the part behind the mesencephalon, as from it all the cerebral nerves originate. Thus not only are the optic lobes relatively important as being the centres of vision, but the medulla oblongata is usually very large. In many sharks it forms the largest part of the brain (Gegenbauer). The spinal lobes of the electric fishes are differentiations of this portion of the encephalon.

In the *Amphibia* the hemispheres are larger, and are divided into two parts (see fig. 17, B). In the *Urodela* (siren, proteus, triton, newt) the mesencephalon remains small, and consists of one lobe, but in the *Anura* (frogs, toads, &c.) there is an advance in this part, it being divided into two. In reptiles there is still an advance in the size of the thalamencephalon and mesencephalon, and the prosencephalon is so large as to pass backwards and overlap the thalamencephalon. The cerebellum (metencephalon) is still small, especially so in *Ophidii* (serpents) and *Saurii* (lizards), but in the *Chelonii* (tortoises, &c.) and in *Crocodyli* (crocodiles, alligators) it is larger. In the crocodile there is a transverse grooving of the cerebellum, giving rise to foliation or laminar division, which is carried much farther in birds and mammals, indicating a greater power of co-ordination or regulation of movement.

In birds (fig. 18) the vesicles of the mid-brain are partially hidden by development of the cerebral hemispheres. These are connected by a fine anterior commissure, and they contain a large amount of ganglionic matter bulging into the primitive cavity or ventricles, which are of very small size. The middle portion of the cerebellum shows a distinctly laminated structure and a differentiation into white and grey matter. But there is no pons Varolii, nor corpus callosum, nor fornix, nor hippocampus. In the floor of the lateral

ventricles may be seen a ganglionic mass corresponding to corpus striatum and optic thalamus. The optic lobes are relatively large and show considerable differentiation of structure.

Mammals, even the lower orders, not only show a general enlargement of the cerebral hemispheres, but we find a commissure, the corpus callosum, uniting them. This commissure is of small size and is confined to the fore part of the hemispheres in *Monotremata* (*Ornithorhynchus*, *Echidna*) and *Marsupialia* (kangaroos, &c.), and in some of the *Edentata* (ant-eaters, sloths, &c.), but it gradually extends farther and farther back as we ascend to the higher orders. The chief changes thus occur in the prosencephalon. In the lower orders of mammals the hemispheres are comparatively small and simple, and do not present any division into convolutions, and very little distinction even of lobes. The cerebral hemispheres gradually grow backwards, covering mid-brain, cerebellum, and medulla oblongata, as we find in the higher *Primates* (monkeys, apes, and man). There is also a general enlargement of the brain and of the cranial cavity. The development of a posterior lobe only takes place in the higher orders, and in these also the enlargement of the frontal lobes brings the front of the cerebrum more and more over the nasal cavities, causing a development of forehead. This also explains how the olfactory bulbs in more highly-formed brains are thrown below the frontal part of the hemispheres, instead of originating at their anterior borders. But the internal arrangements of the brain also become more complicated. The fornix, already described, establishes, by its longitudinal commissural fibres, a connexion between the anterior and posterior lobes of the cerebrum. In the *Monotremata* and *Marsupialia* the mid-brain retains a bifid form, constituting the optic lobes, or corpora bigemina, but in all higher animals each is divided into two by a transverse groove, forming the corpora quadrigemina, of which the anterior pair is the largest. As we ascend also, we find the surface of the brain becoming more and more convoluted (see figs. 19 and 20). This is the general fact; but whilst the convolutions are most numerous and deepest in the highest orders there is no regular gradation, as in each group there are very great variations in the degree of convolution (Allen Thomson). Thus in the *Monotremata* the *Echidna* has a more convoluted cerebrum than the *Ornithorhynchus*, whilst in the *Primates* the brains of the marmosets show a comparatively smooth non-convoluted surface, in striking contrast to the rich convolutions seen on the brains of the higher monkeys and of the apes. It is important to note that the cerebellum also becomes more and more complicated as we ascend from the lower to the higher groups. At first merely a lamina or band, as seen in fishes and amphibia, it is a centrally differentiated body in crocodiles. In birds there is an indication of a division into three portions, a central and two lateral, whilst the central is by far the larger, the two lateral being feebly developed. In *Monotremata* the central portion is larger than the lateral, but, whilst it is larger in *Marsupialia*, *Edentata*, and *Cheiroptera* (bats, &c.), it is clear that the lateral portions are increasing in size so as to make the disproportion less. But in *Carnivora* (felines, hyena, otter, bear, &c.) and in *Ungulata* (sheep, ox, camel, rhinoceros, horse) the lateral lobes, or hemispheres, of the cerebellum develop to a much greater size; and in most of the *Primates* they are much larger than the median portion, which is now called the worm or "vermiform process." As regards the development of the spinal cord continuous with the medulla oblongata, it need only be said that it does not show any marked peculiarities of structure in different animals. The grey matter from which nerve-fibres originate and in which they end is found in the centre of the cord, and it is most abundant in the regions associated with the development of limbs. The white matter is external, and, in the cords of the higher animals, can be differentiated by fissures into columns, the special functions of which will be hereafter considered. The size of the cord is influenced by the masses of nerves given off from it, so that it attains its greatest thickness and development in the four higher

FIG. 18.—Typical brain of bird. A, view from above; B, lateral view of a bisected brain. divisions of the vertebrates possessing limbs. Thus, too, are formed cervical, dorsal, and lumbar enlargements, contrasting with the more uniform and ribbon-like form of the cord in fishes, although even in these there are special enlargements corresponding to the points of exit of important spinal nerves.

Size and Weight of Brain.—The gradual increase in the size of the brain, as compared with that of the body, which is observed as we rise in the animal scale, has some intimate proportional relation to a corresponding increase of the nervous and mental endowments. Information as to the size of the brain may be obtained by direct measurement of dimensions and weight; but as this is often difficult recourse may be had to the measurement of the capacity of the cranium, which contains, however, not only the brain but its accessories, such as membranes and blood-vessels. Details will be found in vol. I. p. 879. After considering the measurements of several thousand skulls made by different observers, the late Dr Allen Thomson arrived at the conclusion that the cranial capacity is on the whole greater among the highly-civilized than among the savage races, and that there is even a very manifest difference to be found between persons of higher mental cultivation and acknowledged ability and those of the uneducated class and of inferior intellectual powers; and he states further that the amount of this difference may be from 5 to 7½ per cent. in persons of the same race, and about double that range in those of different races. Thus, the average adult brain of men in Britain being taken at 3 lb, or, more precisely, at 49½ oz. avoirdupois (women, about 44 to 44½ oz.), at an average specific gravity of 1040, would give a bulk of 82.5 cubic inches of brain-substance; 10 per cent. being deducted for loss by membranes, fluid, &c., the cranial capacity will be about 90 inches. Conversely, the weight of the brain may be calculated from the known cranial capacity. If, therefore, the brain of the uneducated class falls 2.5 oz. below the average, whilst that of the more cultivated persons rises to the same amount above it, or to 52½ oz., we may regard these brain-sizes as corresponding with brain-bulks and cranial capacities of 78 and 87 cubic inches, and of 88 and 97 cubic inches respectively. The average brain-weight of an Australian aboriginal man is about 42 oz., corresponding to a brain-bulk of about 70 cubic inches, and a cranial capacity of about 78 cubic inches. There are, however, great variations in all races. Thus the brain of Cuvier, the great naturalist, weighed 65 oz. avoirdupois, corresponding to a brain-bulk of 108 cubic inches and a cranial capacity of 118 cubic inches; whilst, on the other hand, in Europeans the brain-weight has fallen as low as 32 oz., or a brain-bulk of 53 cubic inches and a cranial capacity of 63 cubic inches. The brains of the anthropoid apes—gorilla, chimpanzee, and orang—are all inferior to man in their dimensions. In the gorilla the brain does not attain more than a third of the weight of the average human brain, and in the chimpanzee and orang it does not reach a fourth, so that the ratio of brain-weight to body-weight in these animals may be as 1 to 100, whilst in man it ranges from 1 to 40 to 1 to 50. It is remarkable that in general among the largest animals of any group the brain does not reach a size proportionate to the greater magnitude of the other organs or of the whole body, so that in the smaller members of the same order a considerably greater proportional size of the brain is observed. Thus in the small marmosets the proportion of the brain-weight to the body-weight may be 1 to 20, or more than double the proportion in man. Similar facts are brought out in comparing the brains of cetaceans, pachyderms, dogs, &c., as shown in the following table.

Table of comparative sizes of Brain and Body.

Examples.	Brain-weight in oz. avoirdupois.	Internal cranial bulk in cub. in.	Whole weight of the body in lb.	Proportion of brain to body weight
Average European man	48 (3 lb)	85 to 88	140	1 to 46
Child at birth	12	22	7½	1 to 10
Chimpanzee	10	19	50	1 to 80
Marmoset	3½	7	6 oz.	1 to 18
Middle-sized dog	3½	6	36	1 to 164
Small dog	2½	4½	7	1 to 45
Elephant	144 (9 lb)	300	6,720 (3 tons)	1 to 747
Pig	6	11	94	1 to 250
Whale	96 (6 lb)	650	134,400 (60 tons)	1 to 22,400
Porpoise	16	30	60	1 to 60

Although the proportion of brain-weight to body-weight in a male child at birth is 1 to 10, yet so rapidly does the brain continue to grow during the early period of childhood that by the age of three years it has attained more than three-fourths of its full size, by the age of seven years it has reached the proportion of nine-tenths, and after this, only by slow and small gradations, it attains the full size between the ages of twenty and twenty-five years.² See PHRENOLOGY.

From this survey of the comparative development of the brain Comparative the following general conclusions can be drawn.

1. The first and essential portion of the cerebro-spinal axis is development the portion forming the spinal cord and medulla oblongata, inasmuch as it is found throughout the whole range of vertebrate brain. existence, and is connected with the reflex or automatic movements on which locomotion, respiration, and the circulation more or less depend, and with the simple sense of contact, or touch, or pressure. This portion is necessary to mere existence.

2. When higher senses are added, such as those of taste, smell, hearing, vision, portions of the anterior part of the cerebro-spinal axis are differentiated so as to form centres. The earliest and most important of these senses (next to touch) is vision, hence the high degree of development of the optic lobes even in the lowest forms; to these are added the optic thalami, which may be regarded as the centres of tactile sensations involving appreciation of differences of touch as to softness, smoothness, hardness, &c., requiring in the periphery special terminal organs. Special centres for hearing, taste, and smell are not differentiated. It is remarkable that the organs relating to the sense of smell are most anterior and most closely related with the prosencephalon, indicating, apparently, that this sense is one of the earliest in appearance, and probably, along with vision and touch, one of the most necessary to existence.

¹ The large cranial bulk in this instance is connected with the enormous size of the roots of the cranial nerves.

² Many of the facts in this paragraph as to size and weight of brain are derived from an unpublished lecture by the late Dr Allen Thomson.

It is equally striking that the origin of the auditory nerves should be placed so far back as in the medulla oblongata and cerebellum, indicating the primitive nature of simple auditory impressions and their relation to co-ordination of movement. The sense of taste originates in nerves springing from the medulla, and in close connexion with those regulating the movements of the tongue and swallowing.

3. When sensations of a simple character are elaborated into ideas and give rise to the physical changes in some way correlated to mental states, involving memory, emotions, volitions, and intellectual acts, a part of the cerebro-spinal axis is differentiated for these functions in proportion to the extent to which such mental phenomena are manifested by the animal. Judging from the facts obtained by comparing animal intelligences, so far as they can be appreciated by us, we have the right to infer that in proportion to the degree of development in size and complexity of structure so is the mental condition of the animal. Taking it broadly, there can be no question that the intelligence of a bird is higher than that of a reptile, amphibian, or fish, and that the intelligence of the higher mammals, such as one of the *Primates*, is superior to that of the lower, as one of the *Insectivora* (hedgehog), or of the *Marsupialia* (kangaroo); and along with the higher intelligence is the more complex brain. There are qualifications to this statement to be afterwards alluded to, but they arise from deficient knowledge and do not vitiate the main conclusion. In proportion, therefore, to the degree of development of the prosencephalon do we find the intelligence of the animal, and we may regard this portion as superadded to the cerebro-spinal axis as the organic mechanism for such mental operations.

4. There is also a correspondence between the degree of development of the cerebellum and the faculty of co-ordination of movement. Movements of the members of the body may be of a very simple character, or they may be very complex. They may be due to the action only of flexor and extensor muscles, causing the limb to move almost in the same plane, or they may be associated with the action of adductor and abductor muscles, by which there may be many kinds of circular or rotatory movements. There is a great difference between the movements of a fish's fin, of a bird's wing, of a horse's fore-leg, and of the arm of a monkey or a man. In the first three they are almost to-and-fro movements, unlike the delicate movements of flexion, extension, pronation, supination, and prehension seen in the latter. Delicacy of movement of the anterior limb reaches its highest condition in man. It may be put generally that simplicity of movement is associated with an imperfectly-developed cerebellum, whilst in animals having the power of complicated movements, involving especially the knowledge of how the limbs are acting at any moment, and of adjustment of movement in special circumstances, the cerebellum is highly developed. From this point of view, the degree of development of the cerebellum is as characteristic of man as the degree of development of the cerebrum. That this is no accidental correspondence will be shown in treating of the functions of the cerebellum.

Having reviewed the physiological anatomy of the cerebro-spinal system, an account will now be given of the more special physiology of the centres composing it,—namely, spinal cord, medulla oblongata, pons Varolii, basal ganglia (including corpora striata, optic thalami, and corpora quadrigemina), cerebellum, and hemispheres of the cerebrum.

Spinal cord.

Spinal Cord.—The spinal cord is described at vol. i. p. 865 sq., but it is necessary here to allude to a few points of physiological importance. The cord consists externally of white and internally of grey matter. The white matter, composed of nerve-fibres, forms a series of strands or columns in each half of the cord. The grey matter in the central part of the cord is arranged in two crescentic masses, and shows under the microscope numerous multipolar cells connected with nerve-fibres and imbedded in neuroglia, or the special connective tissue of the nerve-centres. The neuroglia is composed of a kind of semi-fluid matrix, fibrils, and peculiar cells having numerous branches called "Deiter's cells." (See fig. 21.) These nerve-cells are arranged in definite groups and occupy the same relative position in successive sections, forming the ganglionic or vesicular columns of the grey matter, as follows. (1) Cells

FIG. 21.—Transverse section through spinal cord. AR, antero-medial, and PF, postero-medial fissures; PC, posterior; LO, lateral, and AC, anterior columns; AR, anterior, and PR, posterior nerve-roots; C, central canal of cord, with its columnar epithelial lining. The crescentic arrangement of the grey matter is shown by the darker-shaded portion.

found along the whole of the anterior part of the anterior cornua, many of the processes of the nerve-cells being continuous with the nerve-fibres of the anterior roots of the spinal nerves. This column of nerve-cells has been called the "motor ganglionic column," or the "vesicular column of the anterior cornua." (2) A group or column of nerve-cells at the inner or mesial angle of the base of the posterior cornu, in the middle region of the cord from the third lumbar to the seventh cervical nerve. This is termed the "posterior vesicular column," or "Clarke's column," after the late Mr Lockhart Clarke, who did much to unravel the intricate anatomy of the nerve-centres. The nerve-cell processes are continuous chiefly with nerve-fibres coming from the lateral column. This vesicular column is best developed where the column of the anterior cornu is least so. (3) The third column of nerve-cells is in the outermost portion of the grey matter, midway between the anterior and posterior cornua. Development has shown that at an early period the anterior horns are distinctly differentiated from the posterior, and that the grey matter between them is the last to be formed. The nuclei in the latter may be regarded, therefore, as accessory nuclei. It has also been observed by Flechsig and others that the white substance of the cord also makes its appearance first in the neighbourhood of the anterior and posterior roots. The cord at a very early period consists almost entirely of grey matter, and the columns are superadded in the anterior first, the posterior last. The posterior can also be traced to the cortex of the cerebellum (Flechsig).

The anterior and posterior roots of the spinal nerves are attached

along the sides of the cord, opposite to the corresponding cornua of grey matter. Some of the fibres of the anterior roots end in nerve-cells in the anterior cornu. Others pass through the grey matter and cross to the other side of the cord through the anterior commissure, a layer of white matter at the bottom of the anterior median fissure. A third set passes to the anterior part of the lateral column and to the posterior cornu.

Fig. 22.—Diagram to illustrate the course taken by the fibres of the nerve-roots on entering the spinal cord (Schäfer; Quain's *Anatomy*). a, a, two funiculi of anterior root of a nerve; 1, 1, some of its fibres passing into lateral cells of anterior cornu; 1', 1', others passing into mesial cells of same cornu; 2, 2, fibres passing to lateral column of same side without joining nerve-cells; 3, 3, fibres passing towards posterior cornu; 4, 4, fibres passing across anterior commissure, to enter nerve-cells in anterior cornu of other side; p, funiculus of posterior root; p', fibres of its external or lateral division coming through and around gelatinous substance of Rolando; some of these (5) are represented as becoming longitudinal in the latter, others (6, 6) as passing towards anterior cornu, either directly or after joining cells in posterior cornu, and others (7) as curving inwards towards grey commissure, entering into posterior column and then becoming longitudinal; p'm, fibres from a posterior root which had joined the cord lower down and entered posterior column, now passing into the grey matter at root of posterior cornu. Of these, 8 is represented as entering Clarke's column, 9 as curving round this and coursing to anterior commissure, and 10 as passing towards anterior cornu,—the axis-cylinder processes of the cells of Clarke's column are shown arching round and taking the direction of the lateral column; amf, anterior median fissure; pmf, posterior median fissure; cc, central canal; SR, substantia gelatinosa of Rolando.

of the cord is seen in the table under medulla oblongata below.

The spinal cord acts (1) as a transmitter of motor and sensory—or centrifugal and centripetal—impressions between the encephalon and the periphery, and (2) as a reflex centre.

1. *Transmission of Motor and Sensory Impressions.*—Each spinal Motor nerve, as already mentioned, is connected with the spinal cord by and two roots, an anterior and a posterior. Section of a number of sensory anterior roots causes paralysis of motion of muscles on the same impression side of the body, whilst irritation of the distal or peripheral end of the divided roots causes twitchings or tetanus of the muscles. Neither section nor irritation has any effect on sensation. Hence the anterior roots contain motor fibres, carrying impressions from

the cord outwards. Again, section of a number of posterior roots is followed by loss of sensation of a part of the body on the same side, and, if the proximal ends of the divided roots—those next the cord—be irritated, painful sensations are excited. The posterior roots, therefore, contain sensory fibres, carrying impressions into the cord from the periphery. As we have seen, these roots are connected with the grey and white matter of the cord, and it is practically impossible to trace all their ramifications. Recourse must therefore be had to the evidence supplied by experiment (cutting, or by the Wallerian method, p. 26) and by pathological observation. In tracing the path of fibres, what may be called the "developmental method" has been pursued. It has been shown by Flechsig that, "if the development of the cord be carefully observed, the medullary substance of the nerve-fibres is formed later along certain tracts of the white columns than in the rest of the white matter, so that in transverse sections of the cord these tracts are easily distinguishable by their more transparent grey appearance" (Quain, vol. ii. p. 277). If the anterior columns be cut by an incision extending into the grey matter, leaving the posterior columns intact, voluntary movements disappear in the parts below the section. Again, section of the posterior columns and grey matter, leaving the anterior uninjured, enfeebles but does not destroy the power of voluntary movement below the section. Finally, section of an antero-lateral column on one side paralyzes voluntary motion on the same side. From these facts it is inferred (a) that the motor tracts passing from the brain to the periphery are in the antero-lateral columns, and (b) that the fibres forming these tracts are chiefly distributed to the same side of the body. These inferences are supported by pathological observation. In diseases where the anterior horns of grey matter are affected paralysis ensues, with complete flaccidity of the limbs; and if, from hæmorrhage, softening, or the pressure of tumours, the anterior portion of the cord be irritated there are spasmodic twitches of muscles. Complete transverse section of the posterior columns does not abolish sensibility in the parts below; but there is a loss of the power of making co-ordinated movements. Section of the posterior columns and of the antero-lateral columns, leaving only the grey matter in the centre of the cord intact, does not abolish sensibility. Again, section of the antero-lateral columns and of the whole of the grey matter, leaving only the posterior columns uninjured, is followed by complete loss of sensibility in the parts beneath. The inference therefore is that sensory impressions pass through the grey matter. As already seen, many of the sensory fibres connected with the posterior roots decussate in the grey matter. This explains some of the results obtained by Brown-Séquard, that hemi-section of the cord, involving the grey matter, enfeebled sensibility on the opposite side more and more as the section cut deeply into the grey matter; that a vertical section in the bottom of the posterior median fissure caused loss of sensibility on both sides; and that a lateral section, whilst it caused loss of sensibility (anæsthesia) on the opposite side, was followed by increase of sensibility (hyperæsthesia) on the same side,—a curious fact, explained by Brown-Séquard as being due to irritation caused by paralysis of the vessels of the cord on the side of the section. It would appear also that tactile impressions travel, for a certain distance at all events, in the posterior columns. This has been inferred chiefly from the fact that in certain cases of paralysis involving the posterior columns, where the sensation of touch was absent, the patient could still feel a painful sensation, as when a needle was thrust into the skin; whilst in other cases, in which these columns were not affected, the converse held good. In the disease known as locomotor ataxia (see ATAXY and PATHOLOGY, vol. xviii. p. 392) the patient first passes through a period in which there are disorders of general sensibility, especially lancinating pains in the limbs and back. By and by there is unsteadiness of gait when the eyes are closed or in the dark, and to a large extent the patient loses the power of co-ordinating movement. Especially he is unable to judge of the position of the limbs without seeing them; in other words, the so-called muscular sense is enfeebled. At last there is a stage before death in which there is almost complete paralysis. A study of this disease has thrown much light on the physiology of the cord. It is known to be caused by a slow disorganization or sclerosis of the posterior root-zones, the posterior columns,—slowly passing on to affect the columns of Goll, the lateral columns, and the anterior grey horns, and ultimately involving the cord. The disordered sensations at an early stage, the staggering gait at a later, show that the posterior part of the cord has to do with the transmission of sensory impressions. The man staggers, not because he is paralysed as regards the power of movement, but because, in consequence of the sensory tracts being involved, he does not receive those peripheral impressions which excite or indirectly regulate all well-ordered movements of locomotion.

Spinal
cord a
reflex
centre.

2. *As a Reflex Centre.*—The grey matter of the lower cervical, dorsal, and lumbar regions of the cord may be regarded as composed of reflex centres associated with the general movements of the body, whilst in the upper cervical region there are more differentiated centres corresponding to special actions. The initial excitation

may commence in any sensory nerve; the effect passes to the cord, and sets up changes in the nerve-cells of the grey matter, involving time, and resulting in the transmission outwards along motor fibres of impulses which excite particular groups of muscles. There is an exact co-ordination, with a given strength of stimulus, between certain areas of skin and certain groups of muscles, and thus movements may be so purpose-like as to simulate those of a conscious or voluntary character. Thus irritation near the anus of a decapitated frog will invariably cause movements of the limb towards the irritated point. The activity of reflex centres may be inhibited, as already shown, by higher centres, or possibly by certain kinds of sensory impressions reaching them directly from the periphery. Hence removal of these higher centres is followed by apparently increased reflex excitability. Strychnia and the alkaloids of opium increase it, whilst aconite, hydrocyanic acid, ether, chloral, and chloroform have an opposite effect. In certain pathological conditions also, as in tetanus, or in some slow progressive diseases of the cord, reflex excitability may be much increased. In tetanus the slightest touch, a movement of the bedclothes, the closing of a door, the vibration caused by a footstep, may throw the patient into severe and prolonged convulsions. The earlier formed ganglionic cells are those specially concerned in reflex acts.

Special reflex centres have been clearly made out in the cord. (1) *A cilio-spinal* centre, between the sixth cervical and third dorsal nerves, associated with the movements of the iris. The fibres controlling the radiating fibres of the iris, and found in the sympathetic, originate here (see EYE). Hence irritation of this region causes dilatation of the pupil, an effect not produced if the sympathetic fibres have been divided. (2) *Accelerating* centres, supplying fibres to the sympathetic which ultimately reach the heart, and irritation of these centres quickens the movements of that organ. (3) *Respiratory* centres. The movements of respiration, of a reflex character, involve the action of many thoracic and abdominal muscles. Section of the cord above the eighth dorsal paralyzes the abdominal muscles; above the first dorsal, the intercostals; above the fifth cervical, the serratus magnus and the pectorals; and above the fourth cervical, by paralyzing the phrenics, it arrests the action of the diaphragm. (4) *Genito-spinal* centre. This is in the lumbar region. Irritation causes erection, &c.; destruction or disease is followed by loss of virile power. (5) *Ano-spinal* and *vesiculo-spinal* centres. These, connected with the movements of the sphincter ani and of the bladder, exist in the lower portion of the dorsal and upper portion of the lumbar regions. Disease or injury involving these centres causes involuntary evacuation of the bowel and complete paralysis of the bladder, with non-retention of urine. The bladder may be full whilst the urine constantly escapes in small quantity.

3. *As a Trophic Centre.*—The ganglion-cells in the anterior Cord as cornua undoubtedly have a trophic or nutritive influence upon trophic muscles. This has been determined chiefly on pathological evidence. centre. If these cells undergo atrophy or degenerative changes, the muscles, even though they may be kept periodically in a state of activity by galvanism, become soft and fatty changes take place. There is thus a correlation between the nutritive condition of muscle and nerve-centre, and influences affecting the one affect the other also.

It has been supposed that the cells in Clarke's vesicular column may form the centres in visceral innervation. They are bipolar, like those in the sympathetic, and not multipolar as in the rest of the cord, and the columns are absent in the lumbar and cervical enlargements. The cells are found where nerves come off that influence the viscera, and similar cells are found at the roots of the vagus in the medulla,—a nerve also much concerned in the innervation of viscera.

Inhibition of Reflex Actions.—The reflex actions of the spinal cord may be inhibited or restrained to a greater or less extent by the action of centres in the encephalon, so that pure reflex actions reflex only occur after removal of the cerebrum, or during profound sleep, actions when the cerebrum is inactive. Thus a strong effort of the will may restrain from scratching an irritated part of the skin, whilst the same amount of irritation would certainly cause reflex movements if the will were in abeyance. Such power of voluntary control, however, is limited with respect to most reflex actions, whilst some reflex acts cannot be so influenced. Any movement that may be originated by the will may be inhibited or restrained to a certain extent when the movement is of a reflex character; but, if the movement be invariably involuntary, it can never be inhibited. Thus the ejaculation of semen cannot be voluntarily induced, whilst the reflex act once provoked cannot be arrested (Hermann). That these inhibitions of reflex actions of the cord depend on mechanisms in the brain is proved by the fact that removal of the brain is followed by an increase in the reflex excitability of the cord, and that even section of the cord permits of increased reflex excitability below the plane of section (Setschenoff). Further, after section of the spinal cord in the cervical region, irritation of the lower end arrests reflex movements dependent on reflex centres in the lower cervical, dorsal, and lumbar regions (M'Kendrick).

Medulla Oblongata.—This is the prolongation into the cranium Medulla of the spinal cord so as to unite it with the brain. Strictly speak- oblong- ing, the medulla spinalis and the medulla oblongata form one organ. gata. The columns of white matter of the cord undergo changes in form, structure, and relative position when they pass into the medulla (see vol. i. p. 870). Without again detailing the minute anatomy, it is necessary to show, as in the following table, the connexions of the cord and of the medulla with the rest of the brain.

Columns of the Spinal Cord.	Divided into	Continued in Medulla Oblongata as	Pass on to
Antero-lateral column.	A. Pyramidal tract.	Decussate in anterior pyramids.	Cerebrum.
	b. Anterior, or uncrossed, fibres from the dorsal region of the cord—columns of Türk, or columns of Lockhart Clarke.	Pass under pyramid on same side, and form longitudinal fibres of the reticularis alba in dorsal part of mesial area.	Cerebrum. Corpora quadrigemina.
	B. Cerebellar tract.	Restiform body.	Cerebellum.
	d. Principal tract of anterior column, that is, the antero-lateral column less the fibres in b. Not continued up—probably commissural from one side of cord to the other.
Posterior column.	e. From anterior column.	Pass below olivary body to form part of restiform body. Sometimes called the "band of Solly"—not always present.	Cerebellum.
	a. Posterior white column, or Goll's tract, from middle of dorsal region.
	b. Posterior lateral column, between posterior median column and postero-lateral groove.	Posterior median column, becoming the funiculus gracilis, which, with the expansion called the clava, becomes the posterior pyramids.	Cerebrum.
	c. Funiculus of Rolando, between the posterior lateral column b and postero-lateral groove higher up.	Funiculus cuneatus, forming, with cerebellar tract from antero-lateral column, the restiform body.	Cerebellum.

It is important to note the fact that each column of the cord, through the medulla, is thus connected both with the cerebrum and with the cerebellum. Development has shown that the fibres of the bundles which are first formed develop a medullary sheath at a time when the fibres of the later-formed bundles are non-medullated. "When the cord of a human embryo is examined at the end of the fifth month it will be found that the pyramidal fibres of the lateral columns, the fibres of the columns of Türk, and of the columns of Goll are non-medullated; while the fibres of the anterior and posterior root-zones and the cerebellar fibres of the lateral columns are medullated" (Ross). It would appear, therefore, that the latter are the more primitive structures, and that the former are super-added in the cords of the higher animals. The grey matter of the medulla is broken up by changes in the distribution of the white matter into nuclei or masses of nerve-cells, instead of having the crescentic form seen in the spinal cord. These nuclei are connected with the roots of important cranial nerves, and may be regarded as corresponding with the anterior horns of grey matter, with the posterior horns, and with the grey matter between these.

The following nuclei can be found:—(1) the *hypoglossal* nucleus, for the hypoglossal nerve, the motor nerve of the tongue; (2) a *common* nucleus, for a portion of the spinal accessory, vagus, and glosso-pharyngeal nerves; (3) the *principal* or *lower auditory* nucleus, for the auditory nerve; (4) nuclei for the *sixth* or *abducent* nerve, supplying the external rectus muscle of the eye; (5) nucleus for the *fourth* nerve, supplying the superior oblique muscle of the eye; (6) the *facial* nerve, the motor nerve of the face; (7) the *corpus dentatum of the olivary body*, not directly connected with the roots of nerves, but containing nerve-cells. Some fibres, both of the sensory and motor roots of the *fifth* nerve, originate also as far back as the medulla. The third, fourth, sixth, and hypoglossal nerves belong to the system of anterior motor nerves, related to the anterior cornua, whilst the spinal accessory, vagus, glosso-pharyngeal, and fifth belong to the "mixed lateral system,"—that is, they are related to the posterior cornua and intermediate grey matter.

Like the spinal cord, the medulla may be regarded as containing

tracts for sensory and motor transmission, and as constituting a series of reflex centres for special movements.

1. *As a Conductor of Motor and Sensory Impressions.*—Inasmuch Motor also, as such movements as those of the circulation, respiration, and and vaso-motor action are necessary to life, destruction of the sensory medulla causes almost instant death. Motor fibres coming from transmission the brain above decussate in the anterior pyramids and then run of down the lateral columns of the cord, issuing to the muscles by medulla. the anterior roots of the spinal nerves. Hence, whilst section of an antero-lateral column of the cord will cause paralysis of motion on the same side, section of an anterior pyramid above the decussation causes paralysis of motion on the *opposite* side. But fibres carrying sensory impressions also decussate in the grey matter at the bottom of the posterior median fissure of the cord. It follows, therefore, that disease, such as rupture of a vessel causing a clot in the brain, say in the left corpus striatum and left optic thalamus, causes paralysis both of motion and of sensation on the opposite side,—that is, in the case supposed, there would be right hemiplegia. The path of sensory impressions is probably in the grey matter but the precise course of sensory fibres has not been traced.

2. *As a Reflex Centre.*—Numerous special centres have been referred to the medulla oblongata. Medulla as reflex centre.

(1) *Respiratory* centres, two in number, expiratory and inspiratory, connected with the roots of the pneumogastric nerves. Destruction at once causes cessation of respiratory movements. (2) *Vaso-motor* centre, regulating the calibre of the smaller blood-vessels throughout the body (see p. 30). (3) *Cardiac* centres, probably two in number—one accelerating, associated with the sympathetic; the other inhibitory, connected with the pneumogastric (see p. 29). (4) Centres for *deglutition*, associated with the sensory and motor nerves involved in this process (see NUTRITION, vol. xvii. p. 670). (5) Centre for *voice*, regulating to some extent, through the sterno-cleido-mastoid muscle, the emission of air through the glottis in expiration and phonation. (6) Centre influencing *glycogenesis*, probably by the action of the vaso-motor centre on the blood-vessels of the liver (see NUTRITION, vol. xvii. p. 682). (7) Centre directly influencing *salivary secretion*, from which originate those fibres of the facial, forming the chorda tympani and lesser superficial petrosal, distributed to the salivary glands (see NUTRITION, vol. xvii. p. 672). (8) Centre for the *motor fibres supplying the face and muscles of mastication*. These exist in the facial for the muscles of the face and in the motor portion of the fifth for the muscles of mastication. Further, the medulla receives nervous influences from the higher centres, by which all the centres above enumerated may be more or less influenced.

Pons Varolii.—The pons Varolii is above and in front of the Pons medulla oblongata, and between the hemispheres of the cerebellum. Varolii. It consists of fibres passing in two directions, viz., longitudinally, connecting the brain above with the medulla and cord below; and transversely, connecting the lateral hemispheres of the cerebellum, thus forming the middle peduncles of that organ. Its general position and appearance are seen in fig. 23. Mixed up with these fibres are various nuclei of grey matter connected with the roots of cranial nerves. The most important of these nuclei are—(1) the nucleus of the facial nerve; (2) the motor nucleus of the fifth nerve; (3) the upper sensory nucleus of the fifth nerve; (4) the inner or chief nucleus of the auditory nerve; (5) the outer or superior nucleus of the auditory nerve; (6) the accessory nucleus of the auditory nerve; (7) the nucleus of the sixth nerve. It will be observed that several of these nerves are also connected with nuclei in the

medulla oblongata. Like the cord and medulla, the pons is to be regarded as a conductor of impressions and probably also as a reflex centre. Motor transmission occurs chiefly in the anterior part. As the fibres of the facial nerve decussate in the pons, and then carry influences outwards, unilateral injury or disease of the pons may cause paralysis of the face on the same side as the disease, and paralysis of the limbs on the opposite side if the disease has affected the facial before its decussation in the pons. Usually in cases of paralysis of one side (hemiplegia) from a clot or disorganization in one corpus striatum the paralysis of the face is on the same side as that of the limbs. In diseases of the pons loss of sensibility is a much more

FIG. 23.—Section of medulla oblongata and pons to show the course of fibres. a, superficial, and a', deep transverse fibres of pons; b, b', anterior pyramids ascending at b' through pons; c, c', olivary bodies; d, d', olivary fasciculus in pons; e, e', anterior columns of cord; f, inner part of right column joining anterior pyramid; g, outer part going to olivary fasciculus; h, lateral column of cord; i, the part which decussates at h; k, the decussation of the pyramids; l, the part which joins the restiform body; m, that which forms the fasciculus teres; n, axoniform fibres. 1 and 2, sensory and motor roots of the fifth nerve; 3, sixth nerve; 4, portio dura; 5, portio intermedia; 6, portio mollis of the seventh nerve; 7, glosso-pharyngeal; 8, pneumogastric; 9, spinal accessory; 10, hypoglossal nerve.

rare result than loss of motion, and is always on the opposite side. According to Brown-Séquard, tactile, thermal, and painful impressions pass through the central part of the pons. The numerous centres in the pons are associated in complex reflex movements. Nothnagel has described it as a convulsive centre, because irritation caused severe cramps, but this was no doubt due to irritation of the motor strands passing through it.

Cerebral peduncles. *Cerebral Peduncles.*—These contain both sensory and motor fibres, and they establish a connexion between the cerebellum and the cerebrum, and also between the ganglia at the base,—corpora striata, optic thalami, and corpora quadrigemina on the one hand, and the pons and medulla on the other. Little is known of their functions except that they are conductors. Destruction of one peduncle causes the animal to move to the side opposite the lesion, describing a circle somewhat in the manner of a horse in a circus. Irritation may cause pain or movements of various groups of muscles.

Basal ganglia. *Basal Ganglia.*—As already shown in tracing the development of the cerebro-spinal system, the brain consists of a series of ganglia, in pairs, more or less overlapped by the cerebral hemispheres. These ganglia, termed the "basal ganglia," are usually held to include, from behind forwards, the corpora quadrigemina, the optic thalami, and the corpora striata; but in addition there are bodies meriting an equal amount of attention, inasmuch as they cannot be regarded as belonging to the cerebral hemispheres. These are the locus niger, the red nucleus of the tegmentum, and the corpora geniculata; but we have no knowledge of their functions. No doubt all these ganglia act along with the cerebral hemispheres, so that practically the whole mass forms one organ.

Corpora quadrigemina. *Corpora Quadrigemina.*—These are two pairs of rounded bodies found above the Sylvian aqueduct, which passes between the third and fourth ventricles. They are situated behind the optic thalami, and are intimately related to the crura, and through these to the pons, medulla, and cord. Homologous with the optic lobes seen in the brain of the fish, frog, and bird (see figs. 17 and 18), and in marsupials and monotremes, their relative size to the mass of the encephalon is much less in the brain of man and of the higher animals. These bodies contain grey matter, covered by a thin stratum of white matter. The two posterior bodies are probably connected with the cerebellum by the superior peduncles of that organ; at all events these peduncles disappear under the base of the corpora quadrigemina. The two posterior bodies are also related to the crura cerebri by the prominences on the sides of the crura known as the inner geniculate bodies. Both anterior and posterior bodies, more especially the anterior, are connected with the optic tracts, and finally, the two anterior bodies unite with the optic thalami. (See fig. 24 below; also, plate XVIII., vol. i., fig. 1, g, g.) As shown by their anatomical connexions, the corpora quadrigemina are part of the mechanism of vision. Destruction causes immediate blindness. If, in a pigeon, the encephalon be removed with the exception of these bodies, the iris will still continue to contract on the influence of light. On then destroying one of these bodies, the iris is immobile, and the power of accommodation is lost. As the third cranial nerve (which is known to contain fibres controlling the circular fibres of the iris by which the pupil contracts, and the fibres governing the ciliary muscle by which the eye is accommodated or focused to varying distances) originates in the grey matter of the floor of the Sylvian aqueduct, close to the corpora quadrigemina, it is held that these bodies are the centres of the reflex movements of the iris and of the ciliary muscle. The corpora quadrigemina are also the first recipients of visual impressions. When light falls on the retina changes are there induced which stimulate the optic nerve-fibres, and these fibres carry impressions through the optic tracts to the corpora quadrigemina. What then occurs is matter of conjecture. Whether sensation is there excited, or whether to produce sensation it is necessary that the impulses be sent onwards to the cerebrum, or whether the impressions directly received from the retina may excite, through the corpora quadrigemina and adjacent ganglia, reflex movements (like those of the somnambulist, who may see so that his steps are taken rightly, but who may at the same time not see consciously), are all speculative questions. We know that these bodies are concerned in the movements of the iris and of the ciliary muscle, but their great proportionate size in lowly-formed brains indicates that this is probably a secondary function, and that they are largely concerned in the phenomena of consciousness of light and colour.

Optic thalami. *Optic Thalami.*—These are two ganglionic masses placed behind the corpora striata and in front of the corpora quadrigemina. The internal surfaces are seen chiefly in the third ventricle, the upper surfaces in the same ventricle and the lateral ventricles (see vol. i. pp. 875, 876, figs. 74 and 75), whilst the external and under surface of each thalamus is united with other parts of the brain. The under surface receives fibres from the crus cerebri, whilst the upper surface is covered by fibres which diverge and pass between the thalamus and a mass of grey matter in the extra-ventricular portion of the corpus striatum (called lenticular nucleus), to form a white layer called the "internal capsule." From the internal capsule, which thus contains fibres from the optic thalamus, fibres

radiate outwards to the surface of the cerebral hemispheres. The under surface of the thalamus is connected with the tegmentum,—that is, with the layer of fibres forming the upper surface of the crus cerebri. They also receive fibres from the corpora quadrigemina, and according to some authorities from the superior peduncles of the cerebellum. The substance of the thalamus contains nerve-cells, scattered and also aggregated into two nuclear masses, but the relations of these to nerve-tracts have not been ascertained. It is important physiologically to notice that the thalami receive fibres from the back of the crura, and therefore are probably related to the posterior or sensory portion of the spinal cord.

There is still much uncertainty as to the functions of the optic thalami. The most commonly received opinion is that they are centres for the reception of peripheral impulses, which they may elaborate and transmit forwards to the corpora striata, or directly to the cerebral hemispheres. If the sensory impulses received by the optic thalami are sent to the corpora striata, and by these transmitted downwards and outwards through the crura cerebri, then reflex actions may occur in which the basal ganglia are the centres; but, if the impulses are sent up, in the first place, to the cerebral hemispheres, and by these transmitted down to the corpora striata, then the action must include the higher mechanism of the grey matter of the hemispheres. In the first case it is supposed by those who hold that consciousness is specially connected with the grey matter of the hemispheres that the action would be purely reflex and unconscious. Experiment has not thrown much light on this problem, owing to the deep-seated situation of these bodies rendering the results of operative interference untrustworthy. The little that has been done shows that injury to them does not cause paralysis of motion. Nor can it be said that such injuries cause loss of sensation, the only phenomenon observed being that the animal places its limbs in anomalous positions, and does not seem to be aware of having done so. Meynert is of opinion that the optic thalami fulfil the same functions as to tactile impressions—that is, impressions on the periphery of the body—that the corpora quadrigemina do for visual impressions—that is, impressions on the retina. In cases of apoplexy in which these bodies are involved there are always sensory disturbances on the side opposite the lesion. This would lead to the inference that the optic thalami are the sensory ganglia of the opposite sides of the body. They are not, however, the first ganglionic apparatus through which sensory impressions pass, but they probably co-ordinate in some way centripetal impulses before these are sent to the cerebral hemispheres, where they are correlated with feeling. Further, as the old name "optic thalami" indicates, these ganglia are concerned in some way in vision, because, if seriously injured, blindness, or at all events disturbance of vision, is one of the constant results. This favours the view that they are the "middlemen" between special sensory centres and the higher centres of the cerebrum.

Corpora striata.—These ganglia, sometimes termed the "ganglia Corpora of the cerebral hemispheres," situated in front and on the outer side of the optic thalami, are seen in the lateral ventricles. (See vol. i. pp. 875, 876, figs. 74 and 75.) The greater part of each is imbedded in the white substance of the hemisphere (extra-ventricular portion), whilst the part seen in the floor of the lateral ventricle is called the intra-ventricular portion. Each of these contains a nucleus of grey matter, the *nucleus caudatus* in the intra-ventricular and the *nucleus lenticularis* in the extra-ventricular. The latter is separated internally from the intra-ventricular portion by a layer of white matter called the "internal capsule," whilst on the outer side there is another layer of white matter called the "external capsule," beyond which, again, is a lamina or web of grey matter, called the "claustrum," which separates the external capsule from the island of Reil. The internal capsule is of great importance inasmuch as it is continuous with the *crusta*, a portion of the crus cerebri, which, in turn, is a continuation of the pyramidal fibres of the medulla oblongata and the pons. Multipolar nerve-cells are found in the nucleus caudatus; in the claustrum the cells are small and spindle-shaped. Posteriorly, therefore, the corpus striatum is related by fibres with the optic thalamus; inferiorly, through the internal capsule, with the pyramidal portion of the medulla and cord; and externally and superiorly with the grey matter of the cerebrum. The corpus striatum is a centre for the co-ordination of centrifugal or motor impulses. It may be roused into activity by impressions reaching it directly from the optic thalamus, but probably it usually acts in obedience to impulses coming from the cerebral hemispheres. When a clot of blood is formed in, say, the right corpus striatum there is motor paralysis of the opposite side of the body, and, according to the size of the clot, the paralysis may affect more or less completely the different groups of muscles. Destruction of the two bodies destroys voluntary movement, but the animal may move forwards as in running. Destruction of the nucleus caudatus renders movements of progression impossible, and the animal performs movements of rotation. Nothnagel by injecting a minute drop of a solution of chromic acid destroyed the nucleus lenticularis of a rabbit, with the result of throwing the animal into complete unconsciousness. He also states

that in the corpus striatum of the same animal there is a point, the *nodus cursorius*, the excitation of which caused the rabbit to rush forwards. This observation agrees with the statement of Magendie that, when he injured the corpora striata, the animal seemed to have an irresistible propulsion forwards. Ferrier states that when the corpora striata were stimulated by an interrupted current convulsive movements of the opposite side of the body took

FIG. 24.—Three pairs of cerebellar peduncles (from Sappey, after Hirschfeld and Levellé. Quain). On the left the three cerebellar peduncles have been cut short; on the right side the hemisphere has been cut obliquely to show its connexion with the superior and inferior peduncles. 1, median groove of fourth ventricle; 2, the same groove at the place where the auditory striae emerge from it to cross the floor of the ventricle; 3, inferior peduncle or restiform body; 4, funiculus gracilis; 5, 5, superior peduncles.—on the right the dissection shows the superior and inferior peduncles crossing each other as they pass into the white substance of cerebellum; 6, 6, fillets at the side of crura cerebri; 7, lateral grooves of crura cerebri; 8, corpora quadrigemina.

place; and when the current was powerful the side of the body opposite to the side of the brain stimulated was forcibly drawn into an arch.

Cerebellum.—In connexion with the physiology of this organ it is important to note its connexions with the rest of the cerebro-spinal axis. It has three peduncles: (1) the superior peduncles (see fig. 24)—*crura ad cerebrum*, or processes ad testes—together with the valve of Viessens, connect the cerebellum to the cerebrum; (2) the inferior peduncles, or *crura ad medullam*, are the superior extremities of the restiform bodies; (3) the middle peduncles, or *crura ad pontem*, much the largest, are the lateral extremities of the transverse fibres of the pons Varolii. They act as commissural fibres for the hemispheres of the cerebellum. All these peduncles pass into the interior of the cerebellum at its fore-part. In the interior of the organ, where the peduncles enter, we find a nucleus of grey matter, the *corpus dentatum*. The cortical substance consists of two layers,—an outer *molecular* layer, consisting of a delicate matrix containing a few round cells and fibres, and an inner or *granule* layer, containing granules or nucleated corpuscles closely packed together. The corpuscles are from $\frac{1}{100}$ th to $\frac{1}{200}$ th of an inch in diameter, and are mixed with a network of delicate nerve-fibres. At the junction of the granular layer with the molecular layer there are peculiar large cells called "Purkinje's cells." They are flask-shaped and about $\frac{1}{100}$ th to $\frac{1}{200}$ th of an inch in diameter, and the long process is directed towards the surface of the cerebellum (see fig. 25). The white centre of each lamina consists of delicate nerve-fibres, the terminations of which have not been satisfactorily made out. Probably they end in the plexus of nerve-fibres in the granule layer, or in the processes of Purkinje's cells. On comparing the section of cerebrum (fig. 28) with that of cerebellum (fig. 25) the contrast is striking. The structure of cerebellum is more like that of the retina (vol. i. p. 888, fig. 78) than of any other nerve-centre.

FIG. 25.—Vertical section through cortex of cerebellum (Sankey). a, pia mater; b, external layer; c, layer of cells of Purkinje; d, inner or granule layer; e, medullary centre.

Experiments on cerebellum.

Results of Experiments.—The cerebellum is insensible to mechanical excitations. Puncture causes no indications of pain, but there may be twisting of the head to the side. Ferrier states that Faradaic

irritation causes movements of the eyeballs and other movements indicative of vertigo. Section of the middle peduncle on one side causes the animal to roll rapidly round its longitudinal axis, the rotation being towards the side operated on.

If the cerebellum be removed gradually by successive slices—an operation easily done in a pigeon—there is a progressive effect on locomotive actions. On taking away only the upper layer there is some weakness and a hesitation in gait. When the sections have reached the middle of the organ the animal staggers much, and assists itself by its wings in walking. The sections being continued further, it is no longer able to preserve its equilibrium without the assistance of its wings and tail; its attempts to fly or walk resemble the fruitless efforts of a nestling, and the slightest touch knocks it over. At last, when the whole cerebellum is removed, it cannot support itself even with the aid of its wings and tail; it makes violent efforts to rise, but only rolls up and down; then, fatigued with struggling, it remains for a few seconds at rest on its back or abdomen, and then again commences its vain struggles to rise and walk. Yet all the while sight and hearing are perfect. See fig. 26. It attempts to escape, and appears to have all its sensations perfect. The results contrast very strongly with those of removing the cerebral lobes. "Take two pigeons," says Longet; "from one remove completely the cerebral lobes, and from the other only half the cerebellum; the next day the first will be firm on its feet, the second will exhibit the unsteady and uncertain gait of drunkenness."

FIG. 26.—Pigeon from which the cerebellum has been removed.

There is thus a loss of the power of co-ordination, or of regulation of movement, without the loss of sensibility, and hence it has been assumed that in some way or other the cerebellum acts as the co-ordinator of movements.

Co-ordination of Movement.—The nervous mechanisms by which Co-movements are co-ordinated—that is, adapted to specific ends—are dination not thoroughly understood, but a short description of what is of movement-known may be here given. Muscular movements may be either ment, simple or complex. In winking, the movement of the eyelid is effected by two muscles, one bringing the lid down, the other raising it. But picking up a pen from the table, taking a dip of ink, and writing a few words involve a complicated set of movements of the muscles of the trunk, shoulder, arm, forearm, fingers, and thumb. To perform the movements with precision each muscle or group of muscles must act at the right time and to the proper amount. It is also clear that all this is accomplished automatically.

We are not conscious of the requisite combinations; but it must be noted that many of these complicated movements are first acquired by conscious efforts, and that they become automatic only by repetition. Again, in walking, equilibrium is maintained by a delicate series of muscular adjustments. When we swing forward one leg and balance the body on the other many muscular movements occur, and with every change in the position of the centre of gravity in the body there are corresponding adjustments. It would appear that in all mechanisms of co-ordination the first part of the process is the transmission of sensory impressions from the periphery. These sensory impressions may be derived from the skin or muscles, and may be caused by variations of pressure arising in them. Thus, if we lift a heavy weight, as a large stone, by the right hand and raise it to the bend of the elbow we throw the body to the other side by the action of the muscles of that side, thus maintaining the equilibrium. We judge of the amount of force necessary to overcome an obstruction by the feeling of resistance we encounter. All the movements of the body, therefore, give rise to feelings of varying pressures, and these feelings regulate the amount or degree of muscular action necessary to maintain equilibrium, or to perform a requisite movement. This is at first a conscious experience, and a child has to pass through an education, often involving pain, before the nervous mechanisms become automatic and the movement is done without effort. But the ordinary sensory nerves, coming from skin and muscle, are not the only channels by which such guiding mechanisms are set in action. As one would expect, sensory impressions, such as those associated with sight and hearing, may be brought into play.

1. **Peripheral Impressions from Semicircular Canals.**—If the membranous portion of the horizontal semicircular canal in the internal ear of a pigeon be cut, the bird moves its head from side to side, and if one of the vertical canals be divided it moves the head semi-up and down. The effects may pass off in a few days if only one circular canal has been cut. If the canals on both sides be divided the canals. movements are exaggerated and the condition becomes permanent. It will then be observed that the animal has lost the power of co-ordinating its movements. It can rest with only a twitching, perhaps, of the head, but if it attempt to fly or walk its movements are indefinite and irregular, like those of a dizzy person, or like those described as following injury to the cerebellum. The irregular movements do not arise from deafness, or noises in the ears, or partial paralysis, or from an uncontrollable impulse. Any strong sensory

impression, such as holding the bird, supporting its beak, or holding a brilliant light before its eyes, will steady it, and it has been noticed that "it can, even without assistance, clean its feathers and scratch its head, its beak and foot being in these operations guided by contact with its own body." It has been supposed that the semicircular canals are concerned in the mechanism of equilibration, — a view urged chiefly by Mach and Crum-Brown. If a blindfolded man is seated on a horizontal rotating table, such as that used in a lighthouse for rotating or eclipsing the light, and the table is turned round, at first there is a sensation of movement in the same direction as that of the table; then this sensation fades away, until he has no sensation of movement, although the table may be rapidly rotating; finally, if the table be stopped without a jerk there is first a very short period in which there is no definite sensation, which is succeeded by a sense of rapid movement in the opposite direction, often accompanied by a feeling of nausea. Now it is evident that neither sight nor touch nor muscular sensations can give a sense of rotation in these circumstances, and yet it is possible to form a fairly accurate judgment of the angle through which the body has moved. It has been suggested that this is effected by the action of the semicircular canals. The membranous portions are surrounded by a fluid called the "endolymph," and are free to move through a short distance. Hence it has been supposed that rotations more or less rapid must cause variations of tension of the membranous portion. Thus, if the membranous part, especially the ampulla or dilated ends of the canals, lag behind when rotation in one direction takes place, the nerves ending in them will be subjected to a strain; by and by both membranous portions and surrounding parts will be moving with the same velocity, when there will be no strain and no sense of movement; and at last, when the rotatory movement is arrested, there will be a tendency on the part of the membranous portions, as they are floating in a fluid, to move on a little farther than the rest, and thus again produce a strain, causing a sensation of movement in the opposite direction. By similar reasoning it can be shown that if we take the peculiar position of the three canals into consideration any movement in space might be thus appreciated, and these appreciations enter into the judgment we form of the movements. According to this theory, the sense of equilibrium may be largely due to impressions derived from the position of the head, and, as muscular movements required for placing the body in definite positions are determined, as we have seen, by peripheral impressions, the irregular movements of the pigeon, after injury to these canals, may be accounted for. It is not improbable that in the bird, which from the structure of its extremities—feet and wings—can have no peripheral impressions so delicate as those derived from the papillæ of the skin on the extremities of other animals, the sense of equilibrium is maintained chiefly by impressions from these canals, and this may account for the comparatively large size of these organs in birds and fishes. This is in correspondence also with the requirements of birds in the balancings of flight and of fishes in swimming. It is well known that disease or injury of these canals in the human being produces symptoms of vertigo and a diminution of the power of co-ordinated action, as in Menière's disease, showing that the canals, even in man, have similar functions to those in the bird.

Impres-
sions
from eye.

2. *Peripheral Impressions from the Eye.*—Many movements are guided and controlled by the sense of vision. Simply blindfolding a bird usually makes it passive, and it will not attempt either to walk or to fly; the same effects to a less degree may be seen in a mammal; and a blindfolded man will stagger in his gait. The wonderfully accurate movements of the blind in walking are acquired by long and laborious effort, and are guided by the sensations of hearing, of touch, and of resistance. If the optic lobes of a frog be destroyed, its power of balancing itself is lost. There are thus at least three channels by which peripheral impressions pass to the centres and seem to guide or co-ordinate movement: (1) from the periphery, by nerves of ordinary sensibility arising in the skin, muscles, and viscera; (2) from the semicircular canals of the ear, by special nerve-fibres in the auditory nerve; (3) from the eye, by fibres of the optic nerve. How and where these skeins of sensitive impressions are gathered up and so arranged as to call forth the requisite movements can only be conjectured; but the cerebellum is the organ most likely to be concerned in such a mechanism. It is in organic connexion with many of the nerve-fibres conveying sensory impressions. By the restiform bodies it receives many of the sensory fibres of the spinal cord; the auditory nerve has roots intimately related to the cerebellum; and it is fair to assume that there are communications between the corpora quadrigemina and the cerebellum. Stimulation of the cerebellum causes movements of the eyeballs, and disease of the cerebellum is sometimes attended by blindness. How the cerebellum co-ordinates movement is quite unknown, and the difficulty in explaining its functions is not lessened by the clinical fact that extensive disease of this organ may exist without any appreciable sensory or motor disturbance. There is no evidence to support the view of the founders of phrenology that the cerebellum has to do with the sexual functions.

Cerebral Hemispheres.—As these have been fully described in vol.

i. p. 873, it is only necessary here to point out the anatomical facts that assist in explaining the functions of the organ. It is important to observe, first, the general arrangements of the fibres, and, secondly, the arrangement and structure of the grey matter. The white matter of the cerebrum consists of ascending or peduncular fibres, longitudinal or collateral fibres, and of transverse or commissural fibres.

(1.) *Peduncular Fibres.*—The crusta of the cerebral peduncles consists of bundles of longitudinal fibres derived mainly from the anterior pyramid of the medulla. The crust is quadrilateral in form, but in ascending to the hemispheres it becomes flattened from above downwards, so that the fibres spread out like a fan. The fan formed by these fibres is bent into the form of an incomplete hollow cone, the convex surface of which is directed upwards and inwards. Thus the fibres pass between the optic thalamus and the lenticular nucleus, forming the internal capsule. Higher up the fibres pursue their course beneath and to the outside of the thalamus and the caudate nucleus, and over the lenticular nucleus. "Still higher up the internal capsule has spread out from before backwards, while the anterior half forms an obtuse angle with the posterior. The angle where the halves meet is called the knee (fig. 27, K), while the divisions themselves are called the anterior (fig. 27, IK') and posterior segments of the internal capsule" (Ross). On emerging from the basal ganglia the fibres of the internal capsule radiate in all directions to reach the cortex of the brain, giving rise to the appearance called the "corona radiata." The following

FIG. 27.—(After Flechsig.) Horizontal section of brain of child nine months old, only a portion of the right side being shown. *F*, frontal, *TS*, temporo-sphenoidal, and *O*, occipital lobes; *op*, operculum; *In*, island of Reil; *Cls*, claustrum; *jf*, third frontal convolution; *Th*, optic thalamus; *NC*, caudate nucleus; *NC'*, tail of caudate nucleus; *LN*, lenticular nucleus; *II, III*, second and third divisions of lenticular nucleus; *EK*, external capsule; *IK*, posterior division, *IK'*, anterior division, and *K*, knee of internal capsule; *ah*, *ph*, anterior and posterior horns respectively of lateral ventricles; *gcc*, knee of corpus callosum; *sp*, splenium; *mc*, middle commissure; *f*, fornix; *sl*, septum lucidum.

sets of fibres have been traced into connexion with the cerebrum.

(a) Sensory peduncular fibres, derived from the posterior root-zones and the columns of Goll. These are in connexion with the cerebellum; but, as shown by Meynert, Flechsig, and others, many pass up through the pons to reach the crus cerebri, occupying the posterior and external portion of the pyramidal tract. They do not appear to be connected with the optic thalamus and the lenticular nucleus, but pass between them to the cortex. (b) Fibres from the roots of the optic nerves, reaching the brain by what have been called the "optic radiations of Gratiolet." This bundle of fibres issues from the posterior and external border of the optic thalamus, and is closely applied to the peduncular sensory tract in its passage through the internal capsule, and the fibres seem to be connected with the convolutions of the occipital lobe. It is important to note that at least one of the roots of the optic nerve (the internal) passes into the external geniculate body and thence into the anterior bodies of the corpora quadrigemina. Thus there is a path for the passage of impressions from the retina to the cortex of the brain. (c) Fibres from the olfactory lobes have been traced to a junction with the optic radiations of Gratiolet, and pass with them to the convolutions of the cortex of the occipital or temporo-sphenoidal lobe. (d) The pyramidal tract has already been traced through the spinal cord, medulla, and pons. It then goes on, as already seen, to form the internal capsule and the corona radiata, the fibres ending in the parietal lobule, the paracentral lobule, the superior extremities of the ascending frontal and parietal convolutions, probably the posterior extremity of the first frontal convolution, the posterior extremity of the third frontal, and the inferior extremities of the ascending frontal and parietal convolutions,—in short, in the convolutions forming the middle and parietal region of the surface of the cortex. (e) Fibres issuing from the external surface of the optic thalamus to join the internal capsule. These are distributed to the convolutions of the frontal and parietal lobes. (f) Fibres issuing from the external surface of the caudate nucleus, passing also into the corona radiata. (g) Fibres issuing from the superior and internal surface of the lenticular nucleus to join the ascending fibres of the internal capsule. (h) Fibres ascending from the superior peduncle of the cerebellum. Flechsig says that some of the fibres of the superior peduncle of the cerebellum of the opposite side pass uninterruptedly through the red nucleus and along the internal surface of the fibres of the pyramidal tract to

FIG. 27.—(After Flechsig.) Horizontal section of brain of child nine months old, only a portion of the right side being shown. *F*, frontal, *TS*, temporal-sphenoidal, and *O*, occipital lobes; *op*, operculum; *Is*, island of Reil; *Cl*, claustrum; *th*, third frontal convolution; *Tl*, optic thalamus; *NC*, caudate nucleus; *NC'*, tail of caudate nucleus; *LN*, lenticular nucleus; *II, III*, second and third divisions of lenticular nucleus; *EK*, external capsule; *IK*, posterior division, *IK'*, anterior division, and *K*, knee of internal capsule; *ah*, *ph*, anterior and posterior horns respectively of lateral ventricles; *gc*, knee of corpus callosum; *sp*, splenium; *mc*, middle commissure; *f*, fornix; *s*, septum lucidum.

be distributed to the central convolutions of the cerebrum. (f) Fibres issuing from the corpus callosum and descending into the internal capsule. (g) Fibres of the external capsule which ascend from the crura and ultimately reach the cortex through the corona radiata.

In addition to the peduncular fibres above enumerated, all of which belong to what may be termed the system of the internal capsule and corona radiata, fibres from the fornix, tænia semicircularis, outer layer of septum lucidum, and the fillet of the crus also pass from below upwards to the cortex of the hemispheres (Ross).

(2.) *Longitudinal or Collateral Fibres.*—(a) Fibres running immediately below the surface of the cortex, and connecting the grey matter of adjacent convolutions. (b) Fibres in the gyrus fornicatus, a convolution immediately above the corpus callosum. It is said that bands of these fibres arise in the anterior perforated space and pass completely round the corpus callosum to end in the same perforated space, and that offsets of these fibres pass upwards and backwards to reach the summits of the secondary convolutions derived from the gyrus fornicatus near the longitudinal fissure. (c) Longitudinal fibres of the corpus callosum (nerves of Lancisi), connecting the anterior and posterior ends of the callosal convolution. (d) Longitudinal septal fibres, lying on the inner surface of the septum lucidum, and entering into the gyrus fornicatus. (e) The fasciculus uncinatus, passing across the bottom of the Sylvian fissure and connecting the convolutions of the frontal and temporo-phenoidal lobes. (f) The longitudinal inferior fasciculus, connecting the convolutions of the occipital with those of the temporal lobe.

(3.) *Transverse or Commissural Fibres.*—(a) Many, if not all, of the fibres of the corpus callosum pass transversely from one side to the other and connect corresponding convolutions in the hemispheres. This is the generally accepted view; but Professor Hamilton of Aberdeen has recently stated that his preparations show that there is no such commissural system between convolutions, and that the fibres decussating in the corpus callosum are not continued to convolutions on the other side, but pass downwards. (b) The fibres of the anterior commissure wind backwards through the lenticular nuclei to reach the convolutions round the Sylvian fissure. (c) The fibres of the posterior commissure run through the optic thalami.¹

Arrangement and Structure of Grey Matter.—The grey matter in the medulla and basal ganglia has been already considered. A web or sheet of it is also thrown over the surface of the cerebrum, and forms the outer portion of all the convolutions. The cortical substance consists of cells and fibres imbedded in a matrix similar to the neuroglia of the spinal cord. It may be divided into five layers, which merge into each other by almost insensible gradations. The most external layer consists of delicate nerve-fibres, neuroglia, and a few small round cells destitute of processes (see fig. 28). Going deeper we find cells of a characteristic pyramidal form, the largest being in the deepest layer. Their bases are turned inwards, and their apices towards the surface of the convolution. Cleland states that fibres passing from the apices are continuous with the delicate fibres found on the very surface of the cortex. In the ascending frontal convolutions Betz and Mierzejewski have found pyramidal cells two or three times larger than those of other regions of the cortex, and these have been termed "giant-cells." All the pyramidal cells, no doubt, anastomose by their processes, and give origin to the nerve-fibres of the white substance, but it is rarely possible to trace the fibres from cell to cell. A consideration of these anatomical facts, along with those mentioned in connexion with the comparative anatomy of the brain, shows that the cerebral hemispheres are in intimate connexion by fibres with all the other portions of the cerebro-spinal system. Further, they are not only intricate in structure themselves, but the commissural sets of fibres indicate that there is harmony of function between one part and another. In

FIG. 28.—(After Meynert.) Vertical section of a furrow of third cerebral convolution of man. 1, layer of scattered small cortical corpuscles; 2, layer of close-set small pyramidal corpuscles; 3, layer of large pyramidal cortical corpuscles; 4, layer of small close-set irregular-shaped corpuscles; 5, layer of fusiform corpuscles (like those in the claustrum); m, medullary lamina.

¹ In preparing the foregoing sketch of the fibres of the cerebrum the writer is much indebted to Ross, *Diseases of the Nervous System*.

determining the function of so complicated an apparatus recourse must be had to the evidence (1) of development, (2) of comparative anatomy, (3) of human anatomy, (4) of the observed effects of disease before and after death, and (5) of experiment. Facts have already been collected from the first three of these fields of inquiry, all tending to show that the grey matter of the hemisphere is associated with the manifestation of intelligence in its various forms. The phenomena of disease support the same conclusion. Diseases producing slow changes in the layer of grey matter on the cortex are invariably associated with mental disturbance, such as melancholia, mania, or dementia. If the grey matter be suddenly injured or submitted to compression, as by a blow causing fracture and depression of a portion of the skull, or the effusion of fluid consequent on inflammation, unconsciousness is a certain result. So long as the pressure continues there is no consciousness; if it be removed, consciousness may soon return. On the other hand, if the disease affect the white matter of the central portions or the ganglia at the base, there may be paralysis or convulsions without consciousness being affected. All the facts, therefore, of pathology relating to the brain indicate that the grey matter on the surface of the hemispheres is the organ of consciousness and of all mental operations. This statement is now an axiom of medical science, and the basis of the rational treatment of the insane and of all maladies of the central nervous organs.

Two methods of experiment upon the cerebrum have usually been followed, and both have yielded important results.

(a.) *Removal.*—Flourens and the older observers were aware of the fact that as successive slices of grey matter are removed from the surface of the cerebrum an animal becomes more dull and stupid, until at last all indications of perception and volition disappear. A pigeon in this condition (see fig. 29), if carefully fed, may live for many months; to quote from Dalton—

FIG. 29.—Pigeon, in which the cerebrum has been injured or removed.

"The effect of this mutilation is simply to plunge the animal into a state of profound stupor, in which it is almost entirely inattentive to surrounding objects. The bird remains sitting motionless upon his perch or standing upon the ground, with the eyes closed and the head sunk between the shoulders. The plumage is smooth and glossy, but is uniformly expanded by a kind of erection of the feathers, so that the body appears somewhat puffed out, and larger than natural. Occasionally the bird opens its eyes with a vacant stare, stretches its neck, perhaps shakes its bill once or twice, or smooths down the feathers upon its shoulders, and then relapses into its former apathetic condition."

Similar observations have also been made on reptiles and mammals, but the latter survive the operation for a comparatively short time. In watching such an animal it is difficult to divest one's mind of the belief that it still feels and sees and hears. It may be observed that it rarely makes movements unless stimulated from without. Thus it may remain motionless for many hours; but if pushed, or gently touched, it moves. As remarked by Prof. M. Foster—

"No image, either pleasant or terrible, whether of food or of an enemy, produces any effect on it, other than that of an object reflecting more or less light. And, though the plaintive character of the cry which it gives forth when pinched suggests to the observer the existence of passion, it is probable that is a wrong interpretation of a vocal action; the cry appears plaintive, simply because, in consequence of the completeness of the reflex nervous machinery and the absence of the usual restraints, it is prolonged. The animal is able to execute all its ordinary bodily movements, but in its performance nothing is ever seen to indicate the retention of an educated intelligence."

(b.) *Electrical Stimulation of Surface of Brain.*—It is remarkable that, although many of the early workers in cerebral physiology stimulated the surface of the brain by electric currents, they observed no effect, and therefore Magendie, Matteucci, Longet, brain-Weber, Budge, Schiff, and others taught that irritation of the surface of the hemispheres called forth no muscular movements; and it was generally accepted that the grey matter on the cortex of the brain was entirely concerned in the phenomena of sensation, volition, and intellectual action. During the Franco-German war in 1870 Hitzig had occasion to apply galvanism to a portion of the exposed brain of a wounded soldier, and he observed contractions of the muscles of the eyeball. When peace was restored, experiments were made on the lower animals by Hitzig and Fritsch, in which a portion of exposed brain was irritated by a continuous current, and it was observed that the phenomena took place on opening and closing the current. By these experiments the German observers discovered that, when certain areas of grey matter were stimulated, contractions of certain muscles occurred, and they were thus able to map out areas for groups of muscles. Immediately afterwards the research was taken up by Professor David Ferrier of King's College, London, who, using a Faradaic instead of a continuous current, greatly extended the field of inquiry, and obtained many important results, which are not only

Ferrier's
motor
areas.

of value in cerebral physiology but have been successfully applied to the diagnosis of various diseases of the nervous system. The motor areas as determined by Ferrier in the monkey are shown in fig. 30. Dr Ferrier has also indicated the corresponding motor areas in man by carefully comparing the convolutions with those of the monkey.¹ An inspection of the figures shows that the areas which, when stimulated, give rise to definite movements are distributed only over a part of the cortex. As stimulation gives rise to no movements over other regions of the brain, these have been assumed to be connected with psychical states, such as sensation, volition, &c. Much controversy has arisen as to the real

FIG. 30.—A. Left hemisphere of monkey. B. Upper surface of hemisphere of monkey. The numbers in A and B correspond. 1, advance of opposite leg as in walking; 2, complex movements of thigh, leg, and foot, with adapted movements of trunk; 3, movements of tail; 4, retraction and adduction of opposite fore-limb; 5, extension forward of opposite arm and hand, as if to reach or touch something in front; 6, individual and combined movements of fingers and wrists, ending in clenching of fist; 7, supination and flexion of forearm, by which the hand is raised towards the mouth; 8, action of zygomatics, by which the angle of the mouth is retracted and elevated; 9, elevation of ala of nose and upper lip, with depression of lower lip, so as to expose the canine teeth on the opposite side; 10, opening of mouth with protrusion of tongue; 11, opening of mouth with retraction of tongue; 12, retraction of angle of mouth; 13, eyes opening widely, pupils dilating, head and eyes turning towards opposite side; 14, sudden retraction of opposite ear; 15, subiculum cornu ammonis, torsion of lip and nostril on same side. (Ferrier.)

nature of these so-called "motor areas." It has been clearly ascertained that the effects are not due to diffusion of the electric currents influencing other parts of the brain. That there is to some extent such diffusion between the electrodes there can be no doubt, but the exact correspondence between the area stimulated and the movements produced, and the fact that shifting the electrodes a very short distance to one side or another is followed by different results, show that the effect is somehow owing to changes excited by the electric current in that particular area of grey matter. Hitzig, Ferrier, and others have also found that removal of the layer of grey matter of a "motor centre" is followed by enfeeblement of the movements assigned to the area, but in the course of a few days the paralytic symptoms disappear. The latter effect cannot be due to the corresponding centre on the opposite side taking up the work "as subsequent destruction of the latter produced the usual paralysis on the side opposite to the lesion, but did not cause a repetition of the paralysis on the side opposed to the first lesion" (Carville and Duret). It would appear, therefore, that after destruction of a centre on one side some other part of the same hemisphere may take up the functions of the destroyed part. Goltz of Strasburg has removed large portions of the grey cortex (even to the extent of almost the whole of one hemisphere) by a jet of water so as to avoid hæmorrhage, and still recovery of motor power took place after a time, although there remained "clumsiness in the execution of certain movements." His opinion is that the paralytic phenomena are caused by the injury exciting an inhibitory action on lower centres. This view, substantially that advocated for many years by Brown-Séquard does not explain why it is that gentle irritation of the centre by a weak Faradaic current calls forth movements of a definite character. The evidence, therefore, is strongly in favour of the view that there are definite motor areas of grey matter on the cortex,—that is, in ordinary circumstances these areas are intimately related to specific muscles or groups of muscles. It is quite possible, however, that each group of muscles does not depend on one area alone, but on several, whilst it is more intimately related to one than to the others. This would account also for the fact that movements of a group of muscles may be excited by stimulation of other areas than those mapped out by Ferrier and Hitzig. Recently areas associated with definite movements of the thorax, abdomen, and pelvis have been discovered by Horsley and Schäfer, and thus almost all the muscular mechanisms have been connected with some of the cerebral convolutions.

¹ For figures of human brain showing motor areas, see Foster's *Physiology*, 4th ed., figs. 86 and 87, pp. 627, 628.

Ferrier has also attempted to differentiate sensory centres. On Sensory stimulating the angular gyrus he obtained movements of the eye centres, and associated movements of the head, and he regarded the phenomena as being "merely reflex movements on the excitation of subjective visual sensation." He then found that, "when the angular gyrus of the left hemisphere was destroyed, the animal was blind on the right eye soon after the operation, but recovered sight completely on the following day." On destroying the angular gyri of both hemispheres, an animal became permanently blind in both eyes. In neither case was there motor paralysis. By similar processes of thought and experiment he placed the auditory centre in the superior temporo-sphenoidal convolution, the centres of taste and smell at the extremity of the temporo-sphenoidal lobe, and that of touch in the gyrus uncinatus and hippocampus major. On the other hand, Goltz asserts that even after removal of a considerable part of the cortex the animal is not actually blind, but suffers from an imperfection of sight; and he states that he "can no more obtain distinct evidence of localization in reference to vision or other sensations than in reference to movements." Ferrier's view is supported by the observations of Munk, who finds that destruction of a considerable portion of the occipital lobes causes blindness. Munk has put forth the important distinction that there may be blindness in the sense of total deprivation of vision, and "psychical blindness," or the "inability to form an intelligent comprehension of the visual impressions received"; and he supposes that the grey matter of the cortex over the occipital lobes has to do with the elaboration of simple visual impressions into perceptions. In like manner he concludes that other parts of the cortex may have to do with the elaboration of tactile, olfactory, gustatory, and auditory sensations. This is a likely hypothesis, and not very dissimilar to what has been held for many years, the only novelty being that there is localization in these actions. At present the question cannot be regarded as settled; but it may be stated generally that the posterior portion of the brain has to do chiefly with the reception of sensory impressions, and the middle and lateral regions with the transmission outwards of motor impulses. But there still remains the anterior portion. Electrical irritation of the præ-frontal region of the cortex in the monkey causes no motor reaction. Complete destruction causes no paralysis of motion and no sensory disturbance. Dr Ferrier states:—

"Removal or destruction by the cauterization of the antero-frontal lobes is not followed by any definite physiological results. The animals retain their appetites and instincts, and are capable of exhibiting emotional feeling. The sensory faculties—sight, hearing, touch, taste, and smell—remain unimpaired. The powers of voluntary motion are retained in their integrity, and there is little to indicate the presence of such an extensive lesion or a removal of so large a part of the brain. And yet, notwithstanding this apparent absence of physiological symptoms, I could perceive a very decided alteration in the animal's character and behaviour, though it is difficult to state in precise terms the nature of the change. The animals operated on were selected on account of their intelligent character. After the operation, though they might seem to one who had not compared their present with the past fairly up to the average of monkey intelligence, they had undergone a considerable psychological alteration. Instead of, as before, being actively interested in their surroundings, and curiously prying into all that came within the field of their observation, they remained apathetic or dull, or dozed off to sleep, responding only to sensations or impressions of the moment, or varying their listlessness with restless and purposeless wanderings to and fro. While not actually deprived of intelligence, they had lost to all appearance the faculty of attentive and intelligent observation" (*Functions of the Brain*, 1st ed., p. 231).

Thus the frontal lobes appear to have to do with cognition and intellectual action. If so, the grey matter on the surface of the brain may be mapped out into three great areas—an area concerned in cognitions and volitions in front, a motor or ideo-motor area in the middle, and a sensory area behind. These distinctions are no doubt arbitrary to a considerable extent; but, if they are retained as the expressions of a working hypothesis, they are of service. Long ago, and prior to the researches above alluded to, Dr Hughlings Jackson pointed out that disease of certain areas of grey matter on the cortex of the hemispheres may occasion epileptiform convulsions, localized to particular groups of muscles. The theory of the localization of motor functions has been of great service in the diagnosis and prognosis of such diseases. As to the localization of the faculty of language in the third left frontal convolution, founded on pathological evidence, see APHASIA, vol. ii. p. 171.

The functions of the nervous system have now been described; but they are so complicated and so closely related to each other as to make it no easy matter to form a conception of the system working as a whole. The progress of discovery naturally tends to differentiation, and probably to attach too much importance to one organ as compared with the others, so that we are in danger of losing sight of the solidarity of the whole nervous system. Probably every nervous action, however minute and evanescent, affects more or less the entire system, and thus there may be an under-current of nervous action streaming into and out of the nerve-centres, along with a perpetual series of interactions in the centres themselves, contributing to and accounting for the apparent continuity of conscious experience. Certain relations of one nerve-centre to the others are indicated in fig. 31. No one now doubts that consciousness has an anatomical substratum, but the great problem of the relation between the two is as far from solution as in the mess.

days when little or nothing was known of the physiology of the nervous system. Consciousness has been driven step by step upwards until now it takes refuge in a few thousand nerve-cells in a portion of the grey matter of the cortex of the brain. The ancients believed that the body participated in the feelings of the mind, and that, in a real sense, the heart might be torn by contending emotions. As science advanced, consciousness took refuge in the brain, first in the medulla and lastly in the cortex. But even supposing we are ultimately able to understand all the phenomena—chemical, physical, physiological—of this intricate ganglionic mechanism we shall be no nearer a solution of the problem of the connexion between the objective and subjective aspects of the phenomena. It is no solution to resolve a statement of the phenomena into mental terms or expressions and to be content with pure idealism; nor is it any better to resolve all the phenomena of mind into terms describing physical conditions, as in pure materialism. A philosophy that recognizes both sets of phenomena, mutually adjusted and ever interacting, may be no explanation; but at all events it is unpretentious, recognizes facts, and does not delude the mind by offering a solution which is no solution at all. But apart from the ultimate question there is the important one of whether physiologists are on the whole right

in relegating sensation or consciousness entirely to the grey matter of the brain. The facts of comparative physiology are against such an exclusive notion, because we cannot deny consciousness to many animals having rudimentary nervous systems. As already said, research in anatomy and physiology and the observation of disease have driven physiologists to adopt the view that the brain is the organ of sensation. This is no doubt true in the sense that it ultimately receives all those nervous impressions that result in consciousness; but the parts transmitting the nervous impressions are in another sense as much concerned in the production of conscious states as the brain. This view of the matter, put forward by Professor John Cleland in 1870, has not received from psychologists the attention it deserves. His thesis is—

“that the consciousness extends from its special seat so far as there is continuity of the impressed condition; that when an irritation is applied to a nerve-extremity in a finger or elsewhere the impression (or rather impressed condition) travels, as is generally understood, but exists for at least a moment along the whole length of the nerve, and that as soon as there is continuity of the impressed condition from finger to brain the consciousness is in connexion with the nerve and is directly aware of the irritation at the nerve-extremity” (*Evolution, Expression, and Sensation*, Glasgow, 1881, p. 106).

This view is quite consistent with all the facts of nervous physiology and presents fewer difficulties than the one generally held, which drives consciousness into the recesses of the nerve-cells in the cortex of the cerebral hemispheres. It appears to keep clear of the prevailing error in the philosophy of modern physiology,—that of regarding the body and even the nervous system as a vast series of almost independent organs, losing sight of the community of function and interdependence of parts, characteristic of the body of one of the higher animals.

CIRCULATION IN THE BRAIN.

A due supply of healthy arterial blood and the removal of venous blood are essential to cerebral activity. The brain is contained in an osseous case of which the total capacity is variable. The cerebral substance undergoes almost insignificant changes of volume even under a pressure of 180 mm. of mercury. The quantity of blood in the cranium may vary. In the rabbit not more than 1 per cent. of the total quantity of blood of the body (equal to about 5 per cent. of the total weight of the organ) is present at any one time in the brain, whereas in the kidney, by weight, the blood may amount to nearly 12 per cent., and in the liver to as much as nearly 30 per cent. (Foster). If a small round window be made in the cranium and a suitable piece of glass fitted into it, the veins of the pia mater may be observed to dilate or contract if intermediate pressure be made on the veins of the neck. There is

FIG. 31.—M., muscle; SK., skin; REF., reflex centre; INH., inhibitory centre; MOT., motor centre; G.S.E., centre of general sensation; S.S.E., centre of special sensation; S.E.Q., sense of equilibrium; VOL., volitional centre; EM., emotional centre; ID., ideational centre; EY., eye; EA., ear; TA., taste; SM., smell; V., vessel; G., gland; H&V., heart and vessels; EL.C., electric organs in some fishes. The arrows indicate direction of currents, by following which the influence of one centre over another may be studied.

evidently, then, within the cranium some arrangement by which such variations become possible. This is probably accomplished by the anatomical arrangements of the sub-arachnoid spaces. These spaces, containing fluid, communicate freely with each other and with the space surrounding the spinal cord, so that when the quantity of blood increases in the cranium a corresponding quantity of fluid escapes into the spinal space, the walls of which are not inextensible like those of the cranium. In young children, before the fontanelles are closed, the variations of circulation and blood-pressure cause pulsations, of which there are two kinds—those coinciding with the ventricular systole, produced by the pulsation of the arteries at the base of the brain, and those coinciding with expiration. Pressure on the brain-substance beyond a limit leads to paralysis, unconsciousness, and death. The large sinuses probably assist in equalizing internal pressure, and, as inspiration favours the flow of blood from the sinuses, too great distension of these is also avoided. Vaso-motor nerves regulate the calibre of the arterioles of the brain, but we know nothing of the conditions affecting the nerves. Nor do we know how the waste-products of the brain are got rid of. There are no lymphatic vessels, but there are spaces around many of the vessels. These probably communicate with the cavities in the membrane containing the cerebro-spinal fluid, the value of which, as suggested by Foster, “depends in all probability more on its physiological properties as lymph than on its

FIG. 32.—Injected convulsion of cerebrum (Duret). 1, 1, medullary arteries; 1', group of medullary arteries in fissure between two neighbouring convolutions; 1'', arteries of system of arcuate fibres; 2, 2, 2, arteries of grey substance of cortex; a, large-meshed capillary network situated under pia mater; b, smaller-meshed capillary network situated in middle layers of cortex; c, somewhat larger network in internal layers adjoining white substance; c', capillary network of white substance.

mechanical properties as a mere fluid.” The grey matter is much more richly supplied with capillaries than the white matter, as seen in fig. 32.

CRANIAL NERVES.

The general anatomy of these nerves is described under ANATOMY, Cranial vol. i. p. 880 sq., and it remains only to enumerate their functions. Their deep roots have also been alluded to in treating of the medulla oblongata and the pons Varolii above.

1. The *olfactory nerve*. The nerve of smell (see SMELL).
2. The *optic nerve*. The nerve of sight (see EYE).
3. The *oculo-motor or third nerve*,—motor, supplying all the muscles of the eyeball except the superior oblique and external rectus; it also supplies the circular fibres of the iris and the ciliary muscle (see EYE).
4. The *trochlear or fourth nerve*,—motor, supplying the superior oblique muscle.
5. The *trigeminal or fifth nerve*. It has three branches: (A) The *ophthalmic* division of the fifth, or nerve of Willis, is sensory and supplies (a) the skin of the forehead, the eyebrow, the upper eyelid, the root and lobule of the nose; (b) the palpebral and ocular conjunctiva, the mucous membrane of the lacrymal passages, the frontal sinuses, the upper part of the nasal mucous membrane; (c) the cornea, the iris, the choroid, and the sclerotic; (d) the periosteum and bones of the frontal, orbital, and nasal regions; and (e) muscular sensibility to the intra-orbital muscles. It also influences the secretion of the lacrymal gland. It contains the fibres from the sympathetic governing the radiating fibres of the iris (see EYE), and also the vaso-motor fibres for the iris, choroid, and retina. It is associated with the otic ganglion. (B) The *superior maxillary* division of the fifth furnishes sensory branches to (a) the skin of the lower eyelid, also of the nose, upper lip, and skin covering the malar bone; (b) the mucous membrane of the nasal, pharyngeal, and palatine regions, the maxillary sinuses, the gums, the upper lip, and the Eustachian tube; (c) the periosteum of the bones corresponding to its distribution; and (d) the teeth of the upper jaw. It furnishes filaments to the nasal and palatine glands, and prob-

ably to the glands of the velum palati. It contains vaso-motor fibres from the sympathetic for the vessels, and is associated with the sphenopalatine ganglion. (C) The inferior maxillary division of the fifth contains sensory branches to (a) the skin of the cheeks, temples, lower lip, chin, front part of the ear, and external auditory canal; (b) the mucous membrane of the cheeks, lips, gums, front part of the tongue, the mucous membrane of the tympanum, and the mastoid cells; (c) the periosteum of the lower jaw and temporal bones; (d) the teeth of the lower jaw; (e) the temporo-maxillary articulation; and (f) the muscles in the neighbourhood (muscular sensibility). It thus exercises an influence on taste, hearing, and secretion (see NUTRITION). It contains vaso-motor fibres for the blood-vessels. Its motor branch is distributed to the muscles of mastication; and it is related to two ganglia, the otic and the sub-maxillary.

6. The sixth nerve is motor, and supplies the external rectus muscle of the eyeball only.

7. The facial or seventh nerve is purely motor, and supplies all the muscles of expression. It also contains secretory fibres influencing the action of the salivary glands (see NUTRITION). Some assert that the chorda tympani contains gustatory fibres, but the question has not been settled. Claude Bernard found that the facial contains vaso-motor fibres.

8. The auditory or eighth nerve is the nerve of hearing (see EAR). In addition to purely auditory filaments it contains fibres from the semicircular canals having to do with impressions of movement in space (see pp. 38, 39).

9. The glossopharyngeal nerve is sensory to (a) the mucous membrane of the posterior part of the tongue (nerve of taste), the pillars of the fauces, the anterior face of the epiglottis, and the tonsils; and (b) the mucous membrane of the tympanum, the fenestra ovalis and fenestra rotunda (see EAR), the mastoid cells, and the Eustachian tube along with the fifth. It probably supplies motor fibres to the muscles of the pharynx, but this is doubtful. Vulpian states that it contains vaso-dilator fibres for the vessels of the posterior third of the tongue.

10. The pneumogastric or vagus nerve has many complicated actions. (A) It is sensitive to (a) the mucous membrane of all the respiratory passages, including specially the larynx; (b) the heart; (c) a portion of the digestive tube, namely, the base of the tongue, the velum palati, the pharynx, oesophagus, stomach, and probably the duodenum; (d) it confers muscular sensibility on the muscles to which it is distributed; (e) the mucous membrane of the biliary passages; (f) a part of the dura mater corresponding to the transverse and occipital sinuses; (g) the posterior part of the auditory canal. By the laryngeal branches it specially stimulates expiratory movements. (B) It is motor to (a) many of the muscles of the palate; (b) the constrictors of the pharynx; (c) the oesophagus; (d) the larynx by (a) the superior laryngeal to the crico-thyroid muscle and a portion of the arytenoid, and by (b) the inferior or recurrent laryngeal to the rest of the muscles of the larynx; and (e) to the muscular fibres of the bronchial tubes. (C) It contains vaso-inhibitory fibres for the heart. In connexion with this organ the vagus also contains sensory fibres and fibres belonging to the depressor system. (D) It influences secretion in the stomach (see NUTRITION); but it is doubtful whether it has any action on the renal secretion. (E) It influences the production of glycogen in the liver (see NUTRITION).

11. The spinal accessory is a motor nerve supplying the sterno-cleido-mastoid muscle and the trapezius. It gives an important branch to the vagus (internal branch), which supplies all the motor fibres in that nerve distributed to the larynx, except those in the superior laryngeal supplying the crico-thyroid muscle, and also the motor fibres of the vagus sent to the pharynx. According to Heidenhain, it also supplies the vagus with the inhibitory cardiac fibres.

12. The hypoglossal is exclusively a motor nerve supplying the muscles of the tongue and also the sub-hyoid muscles (see ANATOMY). It also contains vaso-motor filaments.

SPINAL NERVES.

Spinal
nerves.

The spinal cord gives origin in its course to thirty-one pairs of spinal nerves, each nerve having two roots, anterior and posterior, the latter being distinguished by its greater thickness and by the presence of an enlargement called a ganglion, in which are found numerous bi-polar cells. The anterior root is motor, the posterior sensory. The mixed nerve after junction of the roots contains (a) sensory fibres passing to the posterior roots; (b) motor fibres coming from the anterior roots; (c) sympathetic fibres, either vaso-motor or vaso-dilator.

SYMPATHETIC SYSTEM.

Sympa-
thetic
system.

The fibres of the sympathetic system consist of two kinds—(1) of grey or gelatinous fibres, destitute of the white substance of Schwann; and (2) of medullated fibres similar to those met with in the cerebro-spinal centres. The grey fibres originate in the ganglia so prevalent in the sympathetic system, whilst the medullated fibres are believed to come from the cerebro-spinal system. The trunk of the great sympathetic nerve consists of a chain of swellings or ganglia, connected by intermediate cords of grey nerve-fibres, and extending nearly symmetrically on each side of the vertebral column, from the base of the cranium to the

coccyx. On this part of the nerve twenty-four ganglia are placed on each side. This great trunk, as it passes along the spine, is connected with the spinal nerves, the connecting fibres being of the two kinds already described. The grey fibres dominate in the sympathetic nerves, and the medullated in the cerebro-spinal; and these two elements are mixed in various proportions in both of the great divisions of the nervous system. At their lower extremities the main trunks of opposite sides generally unite in the middle line; and at the upper ends each trunk, after being connected with the eighth and ninth cranial nerves, extends to the cranium, passes into that cavity along with the internal carotid artery, and there, as well as in other situations, comes into connexion with all the remaining cranial nerves, except the olfactory, auditory, and optic. This conjunction may be effected directly, as with the fourth, sixth, and ninth nerves; or through a ganglion, as the ophthalmic, with the third and fifth; the sphenopalatine, otic, and sub-maxillary, with the fifth and seventh, or facial; the geniculate, with the seventh or facial; the jugular, with the glossopharyngeal; and with the vagus, through one of its own ganglia. On the fibres of the sympathetic distributed to the viscera numerous ganglia, or plexuses in which ganglia exist, are met with, and frequently there is a plexus following the course of each vessel.

As to the functions of the sympathetic, experiment has led to the following conclusions.

(a.) The vaso-motor fibres of the head are supplied by the cervical sympathetic, and originate in the cervical region of the cord, proceeding from it by the anterior roots of the lower cervical and upper dorsal nerves. The fibres supplying the radiating fibres of the iris also come from that region (see EYE).

(b.) The vaso-motors of the upper limbs and of the thorax come (a) from the inferior cervical and superior thoracic ganglia, and (b) from the cord, by communicating branches between the third and seventh dorsal vertebrae.

(c.) The vaso-motor fibres of the lower limbs come from the cord through the sciatic and crural nerves, whilst those of the pelvic organs are derived from the abdominal ganglia of the sympathetic.

(d.) The vaso-motors of the abdominal viscera exist chiefly in the splanchnic nerves; some fibres supplying the stomach appear to be derived from the pneumogastric.

(e.) The splanchnic nerves all arise in man from the thoracic ganglia of the sympathetic—the greater splanchnic from the fifth to the tenth ganglia, the lesser splanchnic from the tenth and eleventh, and the smallest splanchnic from the twelfth ganglion. The splanchnics supply the stomach, liver, spleen, pancreas, intestines, and kidneys. Division causes dilatation of vessels; irritation causes contraction of vessels, and appears also to arrest or inhibit peristaltic motions of the stomach and intestines. Probably they also contain secretory filaments. The functions of vaso-motor nerves have been already described.

A very complete bibliography of works relating to the nervous system will be found in the *Dictionnaire Encyclopédique des Sciences Médicales*, 2d ser., xii. p. 619. For the comparative anatomy of invertebrates consult Gegenbauer, *Elements of Comparative Anatomy* (trans. and rev. by F. Jeffrey Bell and E. Ray Lankester, London, 1878); for the comparative anatomy of vertebrates, Owen, *Anatomy of Vertebrates* (3 vols., London, 1866); for details in human anatomy, Quain, *Elements of Anatomy* (9th ed., ed. by Allen Thomson, E. A. Schafer, and G. D. Thane, London, 1882); for general physiology, Foster, *Text-Book of Physiology* (4th ed., London, 1883); for special details in physiology, H. Beaunis, *Nouveaux Eléments de Physiologie Humaine* (3d ed., Paris, 1881); (specially for the functions of the cranial nerves) Flint, *Physiology of Man* (vol. v., New York, 1872); Ferrier, *On the Functions of the Brain* (London, 1876, also new ed.); Meynert, "On the Brain of Mammals," in Stricker's *Manual of Human and Comparative Histology* (vol. ii., the New Syd. Soc., London, 1872); Flechsig, *Die Leitungsbahnen im Gehirn und Rückenmark des Menschen* (Leipzig, 1876), also "Zur Anatomie und Entwicklungsgeschichte der Leitungsbahnen im Grosshirn des Menschen," in Du Bois-Reymond's *Archiv für Anatomie* (Leipzig, 1881); Gudden, "Experimentaluntersuchungen über das periphere und centrale Nervensystem," in *Arch. f. Psychiatrie* (vol. ii., 1869, p. 713); Hitzig, *Untersuchungen über das Gehirn* (new series, 1874); Goltz, "Ueber die Verrichtungen des Grosshirns," in Pfüger's *Archiv* (1876), also "The discussion on the localization of function in the cortex cerebri," in *Trans. of Inter. Med. Cong.* (vol. i., 1881, p. 218); Munk, *Ueber die Functionen der Grosshirnrinde* (Berlin, 1881); Ross, *Treatise on the Diseases of the Nervous System* (2d ed., London, 1883). (J. G. M.)

PART III.—PHYSIOLOGY OF PLANTS.

THE body of a plant, like that of an animal, consists of one or more structural units which are termed "cells," and in plants, as in animals, the cell consists essentially of an individualized mass of protoplasm.

The probable structure and chemical composition of protoplasm have been already considered. It need only be stated here that the protoplasmic cell-contents do not consist of pure protoplasm, but that the protoplasm contains imbedded in it particles of various substances which may be of the nature of food, or which may have been formed from food, or which are products of the metabolism of protoplasm; it is to the presence of these particles that

the granular appearance of protoplasm is largely due. Moreover, there is present in the protoplasm of the cell, in the vast majority of cases at least, a well-defined, highly-refractive, usually somewhat spherical body, also protoplasmic in nature, the nucleus.

The cell or cells constituting the body of a plant present, in most cases, the important peculiarity that the protoplasm is enclosed in a membrane termed the "cell-wall." This membrane does not consist of protoplasm, but of a substance, cellulose, belonging to the group of the carbohydrates, and having the formula $\alpha\text{C}_6\text{H}_{10}\text{O}_5$. All cell-walls do not, however, consist exclusively of this sub-

stance, though this is probably always the case at their first formation; but the cell-wall may undergo considerable modification during the life of the cell. It may, for example, undergo lignification; it then comes to consist largely of a substance termed "lignin," which is much richer in carbon than is cellulose; this takes place typically in those cells which form woody or sclerenchymatous tissue. Or it may undergo cuticularization, when it comes to consist largely of a substance termed "suberin" or "cutin," which, like lignin, is richer in carbon than cellulose. Or, again, it may become gummy or mucilaginous. These chemical differences are accompanied by differences in the physical properties of the cell-wall. A cellulose cell-wall is extensible, capable of swelling from taking up water into itself by imbibition, and is readily traversed by water. A lignified or cuticularized cell-wall is more rigid and less capable of swelling by imbibition; moreover, a cuticularized cell-wall is almost impermeable to water. A gummy or mucilaginous cell-wall is more extensible and more capable of swelling by imbibition.

Structure of cell.

The structure of the plant-cell is not the same at all periods of its life. When a cell is young the protoplasm occupies the whole of the cavity enclosed by the cell-wall. But in the course of growth the increase in bulk of the protoplasm is not nearly so great as the increase in surface of the cell-wall, so that in the mature cell the protoplasmic contents form merely a rather thin layer known as the *primordial utricle*, which lies in close contact with the internal surface of the cell-wall at all points. There thus comes to be a relatively large cavity in the cell, the *vacuole*, which is filled with a liquid, the *cell-sap*, consisting of water holding various substances, organic and inorganic, in solution. The structure of a mature living cell is then this: it consists of a cell-wall, lined with a layer of protoplasm, which encloses the vacuole, filled with cell-sap.

Functions of cells.

The protoplasm of plants is endowed with all those fundamental properties which are possessed by that of animals. When a plant is unicellular these properties are all exhibited, so far as they are necessary to the maintenance of the organism, by its protoplasm; in other words, all the necessary vital functions are performed by the protoplasm of the single cell of which the plant consists. The performance of all the necessary vital functions by the protoplasm of one cell obtains also in the case of not a few multicellular plants,—in those, namely, in which all the cells are similar to each other in structure and contents. In the great majority of multicellular plants, however, the functions are distributed to a greater or a less extent; there is more or less complete physiological division of labour. In these plants the cells are not all similar in appearance, and their diversity is to be ascribed to their adaptation in different ways to the performance of particular functions. Further, the cells which have undergone modification in some particular direction for the performance of some particular function are grouped together in certain parts of the plant, and these parts are spoken of as "organs." Thus the roots of one of the higher plants are the organs for the absorption from the soil of water and substances in solution; the leaves are the organs for the absorption of gases from the air, and, in virtue of the green colouring-matter chlorophyll, which their cells contain, they are also the organs in which certain important constructive processes are carried on. But the extent to which physiological division of labour is carried out in plants is not nearly so considerable as it is in animals, and accordingly the protoplasm of the different cells of plants exhibits only in a very slight degree that specialization of structure which is so conspicuous in animals.

Absorption.

1. *Absorption of Water and Substances in Solution.*—The bodies of plants, unlike those of the great majority of animals, do not contain any internal cavity into which the food may be taken as a preliminary to its being absorbed by the tissues. The materials of the food of plants are therefore taken up directly from without into the cells of the absorbent organs. The cells which are especially concerned in absorption are, in the higher and subaerial plants, the *root-hairs*,—thin-walled, unicellular, unbranched filaments which are developed from the epidermal cells some way behind the growing-point of the root; in the lower plants, and even in those of the higher plants which lie submerged, all the cells of the plant may take part in absorption. Since the food is directly absorbed by the cells, and since the cells all possess a cell-wall, the materials of the food must be taken up in solution. Salts and other substances are, as a matter of fact, taken up by the absorbent cells in the form of watery solutions. Substances which are soluble in water are dissolved in the water which is present in a greater or smaller proportion in all soils, and of those which are not soluble in water many are brought into solution by the acid sap which saturates the walls of the root-hairs. The actual process of absorption is an instance of diffusion through a membrane,—that is, of osmosis. Only such substances can be absorbed by a root-hair, for instance, as are capable of diffusing not only through the cell-wall but also through the protoplasmic primordial utricle. Further, only such substances can be absorbed by the root-hair as are present in larger proportion in the water to be absorbed than they are in the cell-sap of the root-hair; this inequality between the proportion of any substance in solution in the liquid on the one side and in that of a membrane on the other is a necessary condition of osmosis. Hence, in order that the absorption of any particular substance by the root-hairs may be continuous, it is necessary that the substance in question should not accumulate in the cell-sap; this accumulation is prevented either by the actual consumption (*i.e.*, chemical decomposition) of the substance in the cell or by the withdrawal of it to supply the needs of adjacent cells. In fact, so far as the process of absorption is concerned, the cell-sap of the internal cells of the root stands in the same relation to the cell-sap of the root-hairs as the cell-sap of the root-hairs does to the external liquid; and, as this relation exists between the successive internal layers of cells, there is set up a current of absorbed substances which travels from the surface towards the centre.

Absorption by root-hairs.

Osmosis.

It appears from the foregoing considerations that the amount of any particular salt absorbed in a given time depends upon (1) its diffusibility and (2) its consumption in the plant. Of these two conditions the second is the one which is of real physiological importance, and, if only the given time is sufficiently long, the first condition may be neglected. For instance, let us suppose that a plant is absorbing by its roots two salts—the one (*A*) being very diffusible, the other (*B*) much less diffusible—and that, whilst the former undergoes no change in the plant after absorption, the latter is at once decomposed. Now, if the time of observation is short, it may happen that the amount absorbed of the salt *A* will be found to be greater than that of the salt *B*; but, if the time be extended, the amount absorbed of the salt *B* will certainly be found to be greater than that of the salt *A*. The explanation is that the salt *A* would at first be absorbed very rapidly, on account of its high diffusibility; but the absorption of it would gradually diminish, in consequence of the accumulation of it in the cell-sap of the plant, until it ceased altogether. The absorption of the salt *B*, on the other hand,

Conditions of amount absorbed.

if less active at first than that of *A*, would be continuous, and thus, over a relatively long period of time, the amount of it absorbed would come to be much greater than that of *A*.

Specific absorbent capacity. As a matter of fact, it has been ascertained that when different salts or other substances are presented to the root of a plant they are absorbed in different quantities. And further, it has been ascertained that the different salts are absorbed in different proportions by the roots of different plants; it is, in fact, upon this that the necessity for the "rotation of crops" depends. A striking illustration of this is afforded by a comparison of the amount of silica present in the ash of equal dry weights of gramineous and leguminous plants. According to Wolff—

100 parts meadow-hay contain	27.01	per cent. of silica.
" wheat-straw	67.50	" "
" red clover	2.57	" "
" pea-straw	6.83	" "

The absorption of salts in certain proportions by a plant is the expression of what may be conveniently termed its "specific absorbent capacity." It must not be supposed that this term suggests that the roots possess any selective power by which they absorb this salt and reject that one, or by which this one is absorbed in larger proportion than that one. The question as to whether or not a particular substance will be absorbed is a purely physical one, dependent upon the relation between the molecules of the substance and the cell-wall and primordial utricle which they have to traverse, and in no degree dependent upon the usefulness or hurtfulness of the substance to the plant. The amount absorbed of any particular substance depends ultimately upon the activity with which the plant chemically alters the substance after absorption. To return to the illustration just given. The great difference between the amounts of silica present in the ash of gramineous and of leguminous plants respectively is the expression of the fact that the former are capable of withdrawing relatively large quantities of absorbed silica from the sphere of osmotic activity, and depositing it in the insoluble form in the tissues, whereas the latter can only do so to a comparatively small extent. The specific absorbent capacity of a plant is simply a manifestation of its specific metabolic properties.

Law of absorption. The amount of the various salts absorbed is not, however, exclusively dependent upon the specific absorbent capacity of the plant, for it is materially affected by the composition of the soil. The larger the quantity of any substance presented to the roots, the greater, other things being equal, will be the amount of it absorbed. This does not mean that substances can be absorbed by the roots in solutions of any degree of concentration. It appears that the root-hairs can only absorb very dilute solutions; but for the watery solution of any salt capable of being absorbed there is a certain degree of concentration at which the proportion of the amount of the salt absorbed to that of the water absorbed is the same as that of the solution. If the solution be more concentrated the proportion of water absorbed will be greater, if the solution be more dilute the proportion of salt absorbed will be greater. This is the general "law of absorption" determined by the experiments of De Saussure and of Wolff. It must, however, be borne in mind that, though the *proportion* of salt absorbed is larger in the case of a dilute than of a more concentrated solution, yet the *absolute quantity* of it absorbed from a more concentrated solution in a given time is greater than that absorbed from a dilute solution.

Absorption of gases. 2. *Absorption of Gases*.—An interchange of gases is constantly taking place between the plant and the medium in which it lives—in the case of terrestrial plants, between the plant and the air; in the case of aquatic plants, between

the plant and the water. When the plant is a simple one each of its cells is in direct relation with the external medium; when it is of complex structure there is usually some means provided by which the more internal cells are brought into relation with it, namely, a continuous system of intercellular spaces which communicate with the exterior in terrestrial plants by certain apertures termed "stomata," in the epidermis of the leaves and young stems, and by others termed "lenticels," in the cortical tissue of older stems and of roots.

The gases principally absorbed by plants are oxygen and carbon dioxide. The former is absorbed by every living cell, and at all times; the latter is absorbed exclusively by cells which contain chlorophyll, and by them only when exposed to light. In the more highly-organized plants the cells which contain chlorophyll are confined almost entirely to the leaves, so that the leaves may be regarded as the organs by which these plants absorb carbon dioxide. It has been held that the stomata are of great importance in promoting the absorption of this gas by the leaves, but the experiments of Boussingault prove that this view is not well founded. He discovered, namely, that the upper surface of the leaves of various plants with which he experimented absorbed carbon dioxide more actively than the lower surface, although the upper surface had scarcely any stomata, whereas they were very numerous on the lower. The absorption of carbon dioxide by the leaves is directly effected by the superficial cells.

Gases, like solid substances, are only absorbed in solution by the cells of plants. They may be brought to the surface of the cell-wall already dissolved in water, as in the case of submerged plants, or they may be dissolved from the atmosphere by the sap which saturates the cell-wall, as in the case of land-plants; in either case they reach the interior of the cell in solution. When a gas has been taken up at the surface it diffuses throughout the cell-sap; and in the case of a gas like nitrogen, for instance, which is not chemically altered in the cell, the absorption of it will cease when the cell-sap has become saturated with it. If, however, the metabolism of the cell changes the chemical condition of a gas its absorption will be continuous. This accords with what has been said with regard to substances absorbed by the roots.

Another analogy exists between the absorption of gases and the absorption of substances in solution, namely, that, just as the root can only absorb a solution below a certain degree of concentration, so the leaf can only absorb a gas below a certain degree of pressure. Let us take in illustration the case of carbon dioxide. The pressure of the carbon dioxide in the air is very slight (0.04 per cent. by volume). It was first observed by Percival that an increase in the quantity of carbon dioxide in the air is favourable to the nutrition of green plants; De Saussure found that a considerable increase is prejudicial; and subsequently Godlewski showed that the optimum proportion is from 8 to 10 per cent.,—that is, that carbon dioxide is most readily absorbed by the plant when its pressure is about 200 times greater than in ordinary air. Boussingault found that when leaves are exposed to sunlight in an atmosphere of pure carbon dioxide at the ordinary pressure they cannot decompose it, but if the gas is at a low pressure (in his experiment 0.17 mm. of mercury) they can do so.

Besides oxygen and carbon dioxide other gases are also absorbed by plants, but to a small extent only. Nitrogen is absorbed in small quantities merely in virtue of its solubility and diffusibility; as mentioned above, it is not in any way acted upon by the cells after its absorption. It appears that ammonia may be absorbed from the air in the form of gas by the leaves, and that, when thus absorbed, it contributes to the nutrition of the plant. Other gases,

such as sulphur dioxide, sulphuretted hydrogen, and hydrochloric acid, which are occasionally present in the air as impurities, are absorbed by the leaves, as is shown by the pernicious effects which they produce.

Circulation.

Osmotic
circulation.

It is obviously necessary, in multicellular plants in which certain cells only are in a position to absorb food-materials from without, that these food-materials should be conveyed from the absorbent cells to the remainder of the plant. In no plant is there any organ comparable to the heart of animals by means of which a distribution throughout the tissues of absorbed food-materials is effected. The distribution is accomplished by purely physical means, principally by osmosis. When the cell-sap of a cell becomes charged, by absorption from without or from neighbouring cells, with any substance, diffusion-currents are at once set up between this cell and any adjacent cells the cell-sap of which may contain the substance in question in smaller proportion, and these currents will persist until osmotic equilibrium, as far as this substance is concerned, is established. The diffusion-currents do not flow in any definite direction, but their course is determined simply by inequalities in the chemical composition of the cell-sap of the cells in different parts of the plant. Since in subaerial plants the roots are as a rule the only organs which absorb substances from the soil, and since the cell-sap of their cells is therefore relatively rich in absorbed food-materials, the general direction of the diffusion-currents is from the roots upwards into the stem and leaves.

In cellular plants—that is, in plants which possess no vascular tissue—the distribution of absorbed food-materials is effected solely by osmosis. Many of these plants are small, so that the distribution is effected from cell to cell with sufficient rapidity by this means. Those of them that are large have a very considerable absorbent surface, many of them being aquatic in habit, so that the absorbed substances have no great distance to travel. In vascular plants, more particularly in those which are subaerial in habit, the distribution of the water, holding substances in solution, which is absorbed by the roots is effected to a considerable extent by means of the vascular system. The forces by which the flow of liquid through the vascular tissue is maintained are the following. The first is the

Root-
pressure.

root-pressure. It is a matter of common observation that, when the stems of vascular plants are cut across, particularly in the spring, an escape of water takes place from the surface of that portion of the stem which still remains connected with the root, an escape which may persist for some considerable time. It has been ascertained that this outflow of water takes place under considerable pressure; for instance, Hales observed, in the case of a Vine, that the pressure was sufficiently great to support a column of mercury $32\frac{1}{2}$ inches in height. But the root-pressure not only manifests itself by causing a flow of water from the cut surfaces of stems, it also causes in many plants the exudation of drops of water at the free surface. Drops may commonly be seen on the surface of certain Fungi (*Pilobolus crystallinus*, *Penicillium glaucum*, *Merulius lacrimans*), which are exuded in consequence of the hydrostatic pressure set up in the plant by the active absorption effected by the organs (rhizoids) which here perform the functions of roots. Again, drops are frequently to be found on the margins and at the apices of the leaves, especially the younger ones, of many plants, such as Grasses, Aroids, Alchemillas, Saxifrages, &c. That the formation of these drops depends upon the forcing of water upwards through the vessels by the root-pressure is proved by the fact that, if the stem be cut off from the root and then placed with its cut end in water, no more drops will appear

on the leaves. The water thus forced into the vascular system is not pure water, but a watery solution of various substances, principally salts absorbed by the roots. It is therefore obvious that the root-pressure assists in the distribution of these substances throughout the plant.

In order to understand how the root-pressure is set up it will be necessary to give a brief description of the general structure of the root. It consists of a central fibro-vascular cylinder which is surrounded by several layers of parenchymatous cells, the most external of these layers being in contact with the epidermal layer, certain cells of which are developed into root-hairs. Water is absorbed by the root-hairs and passes from them by osmosis into the subjacent parenchymatous cells. It is obvious, however, that osmosis cannot take place between the cells of the innermost layer and the vessels, for the conditions of osmosis are not fulfilled, inasmuch as the vessels at first contain no liquid. The passage of water from the cells into the vessels can only take place by filtration. For this a certain pressure is necessary, and this pressure is set up by the absorbent activity of the root-hairs and of the parenchymatous cells. The system of cells absorbs large quantities of water, more indeed than the cells can contain, so that at length the resistance of the cell-walls is overcome at what is presumably the weakest point, and water filters into the cavities of the vessels of the wood. There it collects, and it may, under certain circumstances, fill the whole vascular system; then, since absorption is still going on at the surface of the roots, sufficient pressure is set up to cause that exudation of drops on the leaves to which allusion has been made, and, if the stem be cut across, to cause “bleeding” at the cut surface. From the foregoing account it is apparent that the root-pressure is the expression of the absorbent activity of the root-hairs.

But the vessels of the wood do not always contain water. Hales observed that, whereas a Vine will bleed freely if its stem be cut across in the month of April, no bleeding is observed if it be cut in July. And yet it cannot be doubted that the plant is absorbing water by its roots more actively in July than in April. The explanation of these facts is that, although in July the plant is absorbing water actively by its roots, yet it is losing so much in the form of vapour from its leaves that water does not accumulate in the cavities of the vessels. This loss of water in the form of vapour from the general surface of the plant exposed to the air is termed “transpiration.” The parts of the plant which are more especially concerned in transpiration are the leaves. By their structure they are peculiarly adapted for this purpose. The tissue of a leaf is penetrated in all directions by intercellular spaces, which communicate directly with the external air by means of the stomata in the epidermis. In this way a very large surface of moist and thin cell-wall is brought into contact with the air, a condition most favourable to evaporation. Some idea of the activity of transpiration in a plant is afforded by the following determinations made by Hales. In the case of a Sunflower with a leaf-surface of 5616 square inches the amount of water transpired during twelve hours of daylight was 30 fluid oz. (a pint and a half); in the case of a Cabbage with 2736 square inches of leaf-surface the amount of water transpired in the same time was 25 fluid oz. The activity of transpiration is very much affected by external conditions,—the moister the air, the smaller will be the transpiration; and conversely, the drier the air and the higher the temperature, the greater will be the amount of water transpired. Light, too, has a remarkable influence: it has been ascertained by a great number of observers that transpiration is more active in light than in darkness. It seems probable that this is to be attributed largely to the influence of light upon the stomata. Each stoma is

Structure
of root.

Trans-
piration.

Light
and
transpiration.

usually bounded by two cells, termed "guard-cells," which are capable of so altering their form as to close or to open the aperture between them. The form of the guard-cells is dependent upon the amount of water which they contain. When they hold comparatively little water, and are flaccid, their adjacent free surfaces are straight and in contact with each other; the stoma is then closed. When, however, they contain so much water that their cell-walls are under considerable pressure from within—in a word, when the guard-cells are turgid—they curve so that their adjacent free surfaces are no longer in contact, but a space is left between them; the stoma is then open. It appears that the guard-cells become turgid under the influence of light; and it is probably to this open condition of the stomata that the greater transpiration of leaves when exposed to light is to be ascribed.

**Tran-
spiration-
current.** It is obvious that the effect of transpiration upon the distribution of water through the plant is very great. It sets up a rapid current, known as the "transpiration-current," which travels from the roots upwards towards the leaves. Sachs has made some observations as to its rate by means of the lithium-method, which consists in supplying the root of a plant with a solution of a salt of lithium, and determining by means of the spectroscope the length of stem in which lithium could be detected after the lapse of a given time. He estimates the rate per hour to be in *Nicotiana Tabacum* 118 centimetres (46·458 inches), in *Helianthus annuus* 63 (24·793 inches), and in *Vitis vinifera* 98 (38·583 inches). But the water of the transpiration-current holds salts and other substances in solution. It is clear, therefore, that transpiration promotes the distribution not only of water but also of the substances which the water holds in solution. Sachs's experiments go to prove that salts travel in solution in the current; hence it affords a ready means of transport of substances from the roots, where they are absorbed, to the leaves where (as will be shown below) the food undergoes certain changes which fit it for the nutrition of the plant. There is yet another important point to be noted with regard to the physiological significance of transpiration. It has been mentioned that the roots absorb from the soil only very dilute solutions of salts and other substances, so that for any given quantity of a salt absorbed an excessive quantity of water has to be absorbed likewise. It is obvious that the absorption of salts from the soil by the roots can only go on provided that the plant is able to get rid of the excess of absorbed water, and this is effected chiefly by transpiration, though, as mentioned above, an actual excretion of water in the form of drops not unfrequently takes place.

**Channel
of tran-
spiration.** It has been conclusively proved that the channel along which the transpiration-current travels is the fibro-vascular tissue, and that it is the xylem or woody portion of a fibro-vascular bundle which is the conducting tissue. In the case of plants like Conifers and Dicotyledons, in which there is a formation of secondary xylem or wood from a cambium-layer, it is the younger wood, the alburnum, along which the transpiration-current passes. The older wood, the duramen, it is true, usually contains water, but it does not serve as a conducting channel, only as a reservoir. The question now arises as to the mode in which the transpiration-current travels through the wood. Since the vessels contain no water in their cavities at the time when transpiration is most active, it is clear that it is not in the cavities of the vessels that the water of the current travels. Sachs is of opinion that it moves in the substance of the lignified cell-walls. Others, amongst whom Hartig may be especially named, consider that it travels from the cavity of one wood-cell to that of the next by filtration under pressure. The mechanism of conduction would, in

the latter case, be this: the conducting cells contain air and water; when water is withdrawn from one of them the contained air becomes rarefied, and the water in that cell is then subject to a lower pressure than that in neighbouring cells; as a consequence water is forced into the former cell through the thin membranes of the pits in its walls until equilibrium is re-established. Inasmuch, then, as the air in the conducting wood-cells in the leaves is constantly undergoing rarefaction in consequence of transpiration, a current is set up towards the leaves from the stem and the root.

There can be no doubt, however, that, as Hales first pointed out, transpiration has the effect of diminishing the pressure of the gases contained in the cells and vessels. Von Höhnelt has found that, if the stem of a transpiring plant be cut through under mercury, the mercury will at once rise to a height of several centimetres in the vessels, the greatest height being reached in the younger vessels. This rise can only be accounted for by ascribing it to the difference between the atmospheric pressure and the pressure of the gases in the vessels, the lower pressure of the latter being due to the removal of water by transpiration, which necessarily involves an expansion, and therefore also a diminished pressure of the gases. The effect of this so-called "negative pressure" is to set up diffusion-currents of gases from the surrounding tissues into the cells and vessels of the fibro-vascular bundles. It must not be assumed, however, that the vessels are the principal channels in which gases circulate throughout the plant. They circulate principally in the intercellular spaces which communicate with the external air by means of the stomata.

Stating the foregoing facts in the most general terms, it appears that in a plant the food-materials travel by osmosis from the absorbent organs to the organs in which the processes of constructive metabolism are carried on—in one of the higher plants, for instance, from the roots to the leaves—and that the distribution of the food-materials is assisted and accelerated by root-pressure and by transpiration, the fullest expression of this being the transpiration-current in terrestrial vascular plants. And just as there is a current of food-materials tending towards the organs in which the processes of constructive metabolism are carried on, so also there is a current of the organic nutrient substances formed in these organs travelling from them to the other parts of the plant. The final cause of the current is the same in both cases. A given salt, for instance, which has been absorbed by the root travels towards the leaves because it is in some way undergoing chemical alteration in those organs; similarly, a given organic substance formed in the leaves travels from them towards any part of the plant in which that substance is being chemically altered, or, to use a somewhat different expression, is being consumed. The cause of the diffusion in either case is the disturbance of osmotic equilibrium by the chemical alteration of the substance, and the result is a current of the substance from those parts which are relatively rich in it to those which are relatively poor.

Distribution of Organic Nutrient Substances.—In vascular plants the distribution of the organic nutrient substances is, like the conduction of substances absorbed by the roots, assisted by the vascular tissue; but, whereas it is the wood which is the conducting tissue in the latter case, in the former it is the bast or phloem, and more especially the bast-vessels or sieve-tubes. These vessels consist of elongated cells placed end to end, the septa between the adjacent cells being perforated so as to admit of a direct continuity between their protoplasmic contents.

The importance of the wood and of the bast respectively as conducting tissues is well illustrated by the "ringing" experiments which have been repeatedly made on plants,

such as Dicotyledons and Conifers, which have the fibro-vascular bundles arranged in a ring in the stem. When a ring of tissue, extending inwards as far as the cambium-layer, is removed from the stem of a dicotyledonous plant the following facts are to be observed: (1) that the leaves which are borne on branches arising from the stem above the level at which the ring of tissue has been removed will not exhibit any signs of withering; (2) that the part of the stem below the incision will not increase in thickness to nearly the same extent as the part above the incision. From these facts it is clear (1) that the operation in question has not materially affected the conduction of water and food-materials in solution upwards to the leaves, and, since the wood is the only unimpaired tissue, it is obviously in the wood that the upward current travels; and (2) that the operation has materially affected the conduction of organic nutrient substances to the parts below the incision, the diminished growth of these parts being the result of inadequate nutrition; this effect of the operation is to be ascribed, principally at least, to the destruction of the continuity of the bast-tissue.

Laticiferous tissue and vessels. In various families of vascular plants, and in some cellular plants also (certain Fungi), there are to be found cells, forming what is known as "laticiferous tissue," which probably assist in distributing both food-materials and organic nutrient substances throughout the plant. In some plants (*Euphorbiaceæ*, *Asclepiadaceæ*, *Moreæ*, &c.) the cells are quite distinct from each other, and extend from one end of the plant to the other, growing with its growth, so that they attain a very considerable size, and are much branched; these are spoken of as "laticiferous cells." In other plants (*Cichoriaceæ*, *Papaveraceæ*, &c.) the cells are comparatively small, and fuse together to form an intricate network; these are spoken of as "laticiferous vessels." The cells of the laticiferous tissue contain a milky liquid, termed "latex," which consists of water holding inorganic salts, sugar, gum, extractives and proteids, in solution, and holding in suspension resinous and fatty bodies. The cells contain protoplasm in addition, and not uncommonly starch-granules.

Food of Plants.

Food of plants. A rough idea of the nature of its food can be obtained by analysing a plant. It is found that, in the process of incineration, a considerable weight of its dry solid is burned up and given off in the form of gas; this represents the combustible or organic portion of the plant. The incombustible residue, the ash, is found to be of a mineral or inorganic nature. The gases given off are carbon dioxide, watery vapour, and nitrogen, showing that the combustible portion of the plant contained the elements carbon, hydrogen, and nitrogen. In the ash occurs a number of elements, of which the principal are sulphur, phosphorus, potassium, calcium, magnesium, iron, sodium, chlorine, and silicon. But it does not necessarily follow that, because any given chemical element can be detected in a plant, that element is to be regarded as part of the food of the plant, for, as has been already pointed out, plants may absorb substances which in no way contribute to their nutrition, or are even injurious. When an element enters into the chemical composition of the substances of which the organized structure of the plant consists (as C, H, O in starch and cellulose, C, H, O, N, S, P in proteids), then it is clear that this element must form part of the food; but, when, as in the case of the rest of the elements mentioned above, an element does not thus contribute to the building up of the organized substance of the plant, its admission to the rank of a food-material must be the subject of direct experiment. It has been ascertained that many of the elements enumerated above,

though, so far as is known, they are not essential constituents of the organized structure of the plant, are nevertheless essential to the maintenance of its life; they may not, indeed, go to build up the plant-substance, but in some way or other they promote the metabolic processes.

The method which has afforded the most valuable results Water-bearing upon the relative physiological importance of culture. various food-materials is that which is known as "water-culture." It consists in growing plants with their roots immersed in water holding certain salts in known quantities in solution. The mixture of salts can, of course, be varied at pleasure, and the effect upon the plant of the absence of certain elements, as of their presence in smaller or larger quantities, can be observed. Further, by an analysis of that portion of the solution which remains unabsorbed at the close of the experiment, the proportion in which the various salts have been absorbed can be ascertained.

The elements of the food of plants may be conveniently classified into two groups, the first consisting of those which enter into the composition of organized plant-substance, the second consisting of those which, without actually entering into the structure of the plant, are essential to the proper performance of the metabolic processes. To the first group belong the elements C, H, O, N, S, P; to the second, K, Ca, Mg, Fe, Cl (?).

We will now briefly discuss the form in which the various chemical elements are absorbed, and their use in the economy of the plant, beginning with those which enter into the composition of organized plant-substance. A few words will also be said about those elements, such as sodium and silicon, which, though always present in the ash of plants, appear to have no real physiological significance as far as nutrition is concerned.

Carbon.—This element constitutes a large percentage of the total Food dry weight of plants. It enters into the composition of all the elements. organic substances, such as starch, cellulose, and other carbohydrates, fats and other hydrocarbons, proteids, organic acids, alkaloids, &c., which may be present in plants. The form in which carbon is absorbed depends upon the nature of the plant. It may be broadly stated that all those which contain chlorophyll absorb their carbon in the form of carbon dioxide, whereas those which do not contain chlorophyll absorb their carbon in the form of more complex carbon compounds which contain C, H, and O, and in which the C is directly combined with H. Moreover, in green plants it is only those cells which contain chlorophyll that can absorb carbon dioxide, and this only under the influence of light. It must not be assumed, however, that plants containing chlorophyll are incapable of absorbing complex carbon compounds. It is known from the researches of Darwin and others that the "insectivorous" plants absorb such compounds by their modified leaves, and it is known also that a number of green plants, such as the Mistletoe, the Rattle, and others, live parasitically on other plants. It has indeed been proved by direct experiment that green plants can absorb substances such as urea, glycocoll, asparagin, leucine, tyrosine, which are all highly complex carbon compounds. The physiological distinction to be drawn between plants which do and those which do not contain chlorophyll is really that the former are capable of assimilating carbon in a simple compound, such as CO₂, whilst the latter are incapable of doing this, and require, therefore, compounds of more complex constitution. Plants which do not contain chlorophyll are either parasites (that is, they live upon other living organisms) or saprophytes (that is, they live upon the products of the waste and decay of other living organisms). The plants which do not contain chlorophyll are the Fungi and a few Phanerogams, — *Epipogium Gmelini*, *Cuscuta*, *Monotropa*, *Lathræa*, *Corallorhiza*. Of these the Fungi include both parasites and saprophytes; *Epipogium Gmelini* is a saprophyte, *Cuscuta* a parasite, and *Monotropa* may apparently be either the one or the other. The *Orobanchææ*, which are parasitic, and *Neottia*, which is saprophytic, have not a green colour, but small quantities of chlorophyll have nevertheless been detected in them.

Hydrogen.—This element is absorbed by all plants in the form of water and of ammonia and its compounds; it may also be absorbed in the form of organic compounds.

Oxygen.—Oxygen is taken up either in the free state, or in combination in the form of water or of salts; it may also be absorbed in the form of organic compounds. The free oxygen absorbed is especially concerned in the processes of destructive metabolism, the combined oxygen in those of constructive metabolism.

Nitrogen.—Nitrogen is absorbed in the form of ammonia and its compounds and of nitrates; it may also be absorbed in the form of organic nitrogenous compounds. The researches of Lawes, Gilbert, and Pugh, as also those of Boussingault, have proved that plants are incapable of assimilating free nitrogen. It appears that, on the whole, nitrogen absorbed in the form of ammonia compounds is more readily assimilated by plants than nitrogen absorbed in the form of nitrates. Pasteur has shown, for instance, that the Yeast plant cannot assimilate nitrates.

Sulphur.—Sulphur is absorbed from the soil as sulphates, those of ammonium, potassium, magnesium, and calcium being the most advantageous. It may also be absorbed to some extent in the form of organic compounds.

Phosphorus.—Phosphorus is absorbed from the soil in the form of phosphates. Besides being a constituent of certain substances allied to the proteids, such as nuclein and plastin, phosphorus seems to bear an important relation to certain of the metabolic processes. Phosphates are to be found especially in those parts of plants which are rich in protoplasmic cell-contents. It appears that a supply of phosphates promotes considerably the assimilation of nitrogen by the plant.

Potassium.—Potassium is absorbed in the form of a variety of salts, of which the chloride is the most advantageous form, according to Nobbe. Like phosphorus, it is to be found in largest quantity in those parts of plants which are rich in protoplasmic cell-contents. It appears to have an important influence on the constructive metabolic processes of plants which contain chlorophyll. Nobbe found, in the case of a Buckwheat plant, that in the absence of a supply of potassium its growth was diminutive, and that the amount of starch in the plant was very small. On the addition of potassium chloride to the water-culture the starch-grains became more numerous in the chlorophyll-corpuscles, and made their appearance also in the tissues of the stem. The precise significance of potassium in relation to these processes is not known. Liebig was of opinion that it played an important part in the distribution of carbohydrates throughout the plant, but this view has not been confirmed. It appears rather that the facts upon which this view was based point to an effect due not to the potassium itself but to the particular salt of it which was absorbed (see "chlorine" below). There can be no doubt, however, that potassium bears some important relation to the formation and storing up of carbohydrates, for it is always present in large quantity in organs, such as leaves, tubers, seeds, &c., in which these processes especially take place.

Calcium.—The compounds in which calcium is usually absorbed are the sulphate, phosphate, nitrate, and carbonate, the last-named salt undergoing decomposition in the process. It appears that the chloride is injurious to plants. The precise use of calcium is unknown. It very commonly occurs in the cells of plants in the form of crystals of the carbonate or the oxalate, and possibly one of its important functions is to form insoluble salts with acids which are of no further use in the plant, and are even injurious to it.

Magnesium.—Like calcium, this may be advantageously absorbed in the form of all its salts, except the chloride. Nothing definite is known as to its use.

Iron.—It appears that iron may be absorbed in the form of any of its salts. It is known to be essential only to those plants which contain chlorophyll. If a seedling be cultivated by the method of water-culture, with its roots in a solution which contains no iron, the leaves formed will be successively paler in colour until at length they are nearly white; in this state the plant is said to be "chlorotic." If a small quantity of a salt of iron be then added to the solution in which the roots are, or if the pale leaves be painted over with a dilute solution of iron, they will soon become green. Iron, therefore, plays an important part in connexion with the formation of the green colouring-matter chlorophyll. It is still a debated question whether or not iron enters into the composition of the chlorophyll-molecule.

Chlorine.—Chlorine is absorbed from the soil in the form of chlorides. The evidence as to its significance in the nutrition of plants is conflicting. Nobbe, Leydhecker, Beyer, and more recently Farsky have observed that water-cultures of Buckwheat, Barley, and Oats do not flourish when grown in solutions containing no chlorides, and since the chlorophyll-corpuscles of the plants become crowded with starch-grains it was thought that chlorine had some importance in connexion with the translocation of carbohydrates. Knop and Dworzak have observed, on the other hand, that Maize plants will grow well in solutions containing no chlorine, and further, that the accumulation of starch in the chlorophyll-corpuscles may be induced by various abnormal external conditions.

Sodium.—This element is never absent from the ash of plants, and in some cases, especially in maritime plants, it is present in considerable quantity. It might be inferred from its constant occurrence in the ash that sodium is of some importance as a food-material; it was thought, in fact, that it might serve as a substitute for potassium, but this has not been found to be the case. Its constant presence in the ash is due merely to its universal distribution in the soil.

Silicon.—Silicon is absorbed in the form of soluble silicates, and possibly as soluble silicic acid. The silicates are brought into solution to some extent by the carbon dioxide present in the soil, and also by the acid sap of the root-hairs. It is always present in the ash of plants, sometimes in large quantity; in wheat-straw, for instance, it constitutes 67.50 per cent. of the ash (Wolff). It was thought that silicon must be essential to nutrition. Sachs found, however, that a Maize plant will grow well in a water-culture from which it can obtain no silicon. On the other hand, Wolff has ascertained that in the case of Oats the number of perfect seeds formed is greater when the plant is abundantly supplied with silicon.

Constructive Metabolism (Anabolism).

When a plant is adequately supplied with appropriate food-materials, the external conditions to which it is exposed being favourable, it increases in weight, owing to an accumulation of the substances which constitute its organized structure. But this gain in weight is only relative; for side by side with the constructive processes by which the food is converted into the substance of the plant—processes, that is, which have as their result the formation of relatively complex from relatively simple chemical compounds—there are going on destructive processes—processes, that is, which have as their result the formation of relatively simple from relatively complex chemical compounds—which are attended by a loss of weight. The gain in weight by the plant represents the difference between the activity of the constructive and of the destructive metabolic processes respectively. The end of constructive metabolism is the formation of protoplasm. Protoplasm is certainly a very complex substance, though its precise constitution is unknown, and the food-materials of plants are much simpler substances; there must, therefore, be a considerable number of processes to be gone through before protoplasm can be produced from the food-materials. We will now study these processes, and, in the first instance, confine our attention to those which have been ascertained to take place in plants which possess chlorophyll.

It has been already mentioned that a green plant absorbs carbon dioxide when it is exposed to light. Under these circumstances it also increases in weight; it does not increase in weight when kept in the dark, nor when it is kept in an atmosphere from which all carbon dioxide has been removed. The absorption of carbon dioxide is then an indication that the plant is performing certain constructive processes,—that it is assimilating carbon. The absorption of carbon dioxide is accompanied by an evolution of oxygen gas, the volume of the latter exhaled being approximately equivalent to that of the carbon dioxide absorbed. This is an indication that the absorbed carbon dioxide is undergoing chemical change. It seems probable that the change is of the nature expressed by the following equation—

—that is, that from carbon dioxide and water a substance allied to formic aldehyde, or a polymer of it, is formed, free oxygen being evolved. It may be stated generally, with some considerable probability, that the first step in the constructive metabolism of a plant containing chlorophyll is the formation of a non-nitrogenous organic compound. It is just this formation of non-nitrogenous organic substance from carbon dioxide and water that the plant which is destitute of chlorophyll is unable to perform; and it is on account of this inability that the carbon of its food must be supplied to it in the form of organic compounds, as pointed out above. The further processes of constructive metabolism appear to be much the same in all plants, whether they contain chlorophyll or not. The next step is probably the formation of some relatively simple nitrogenous organic substances from the nitrogen of the food and the non-nitrogenous organic substance

which has been either formed in the plant or absorbed as food from without. The nitrogenous substances thus formed are probably crystallizable bodies, such as asparagin and leucin, which all contain nitrogen in the form of the group NH_2 . The derivation of these substances from the nitrogenous food when it contains nitrogen in the form of ammonia (NH_3) is sufficiently obvious. When, however, it consists of nitrates it appears probable that the nitrogen of the nitric acid has to be transformed into the nitrogen of ammonia,—that is, to be combined directly with hydrogen; it is probably owing to their inability to effect this transformation that some plants, as mentioned above, cannot be supplied with nitrogen in the form of nitrates. The first step in this transformation is probably, as Emmerling has pointed out, the decomposition of the absorbed nitrates by the organic acids, especially the oxalic, of the plant; the liberated nitric acid then undergoes chemical change, resulting in the formation of ammonia. It is impossible to say with precision how this is effected, but there can be little doubt that it does take place; some direct evidence is afforded by Hosaeus's observation that ammonia salts were to be found on analysis in a number of plants which had been supplied with manure containing no ammonia. The next process is an increase in the size and complexity of the molecule, attended in certain cases by the introduction of new elements (S and P), the product being one of those substances which are known as "proteids." The last stage is the formation of living protoplasm from the proteid and other organic substances.

Formation of nitrogenous organic substance.

The formation of nitrogenous organic substance may take place in any living cell, and, unlike the formation of non-nitrogenous organic substance, it goes on quite independently of the presence of chlorophyll and of the action of light. But there is evidence to show that in green plants it is especially in the cells which contain the chlorophyll that the process goes on. The experiments by which this evidence has been obtained were made on plants with distinctly differentiated leaves. Emmerling observed in the Bean that, whereas in the root a relatively large quantity of nitric acid could be detected, there was much less in the stem, and in the leaves none at all, and he inferred that as the nitrates are supplied to the leaves they are used up in the formation of organic nitrogenous substance. Further, from the researches of Kellner, Emmerling, Borodin, and others it appears that the leaves contain the above-mentioned crystallizable organic substances, asparagin, leucin, &c., in considerable quantity; and it is quite possible that these substances may be formed synthetically in the leaves, though it is true that they may be formed in other ways as well. Finally, Pott has found that the proportion of proteid in the plant increases from the roots upwards towards the leaves, the proportion in the latter being about twice as great as that in the former of many of the plants which he analysed.

The formation of living protoplasm from the organic substances elaborated from the food necessarily goes on in every living cell. It has been already mentioned that destructive metabolism—that is, processes of decomposition—is active in living cells, and it is especially the protoplasm which is the seat of these processes. The maintenance of the life of the cell is therefore an indication of the fact that the activity of the destructive metabolism is at least equalled by the activity of the constructive metabolism. In a young cell the latter exceeds the former, so that the protoplasm is increased in quantity; then for a time the two are approximately equivalent, until at length the destructive gradually gains the upper hand, and eventually the death of the cell is the result.

Destructive Metabolism (Katabolism).

Just as all the processes by which increasingly complex organic substances are formed in the plant, and which intervene between the food-materials on the one hand and the protoplasm on the other, are designated collectively "constructive metabolism," so all the processes of decomposition by which relatively simple substances are produced from relative complex ones, and which intervene between the protoplasm on the one hand and the excreta and other waste-products on the other, are designated collectively "destructive metabolism." Of all the various processes of destructive metabolism the most fundamental is the decomposition of the protoplasm. It appears that this decomposition is spontaneous—that it is, as Pflüger terms it, a "self-decomposition"; and it is, in fact, only so long as this self-decomposition is proceeding that protoplasm can be said to be living. The destructive metabolism of an organism is not, however, confined to the self-decomposition of its protoplasm; the various complex organic substances which the cells contain may undergo chemical change quite independently of their entering into the metabolism of the protoplasm. The most active agents in producing chemical changes of this kind are certain bodies which are termed "ferments," and are distinguished as "unorganized" ferments from the so-called "organized" ferments, such as Yeast and Bacteria. But little is known as to their chemical composition, and nothing as to the peculiarity of chemical constitution upon which their characteristic properties depend.

The unorganized ferments which have hitherto been detected in plants may be classified, according to the nature of the chemical changes which they induce, in the following four groups.

1. Ferments which convert starch into sugar (diastatic ferments). These have been found to be very widely distributed in plants, and in fact it seems probable that a ferment of this kind is present in all living plant-cells. Their mode of action is generally indicated by the following equation—

2. Ferments which convert cane-sugar into glucose (inverting ferments). A ferment of this kind, termed "invertin," has been obtained from Yeast; it is probable that a similar ferment is present in succulent fruits, for they commonly contain a mixture of cane-sugar and glucose. The following equation will indicate the nature of the process—

3. Ferments which decompose glucosides. The most familiar members of this group are emulsin or synaptase, found in the Bitter Almond; myrosin, in the seed of the Black Mustard; erythrozozym, in the root of the Madder. The following equation represents the decomposition of the glucoside amygdalin by emulsin—

4. Ferments which convert proteids that are indiffusible and may be insoluble in water into others (peptones) which are both soluble and diffusible. These, which are only active in the presence of free acid, are termed "peptic" ferments. They have been found in quantity in the latex of certain plants (*Carica Papaya* and *Ficus Carica*) and in the liquid excretion of carnivorous plants. It is, of course, impossible to represent by an equation the nature of the chemical change which these ferments induce.

It is probable that other ferments than these may be present in plants, but they have not yet been actually obtained. There is probably one which decomposes fats (glycerides) into glycerin and the corresponding fatty acid, thus—

Müntz and Von Rechenberg have pointed out that the quantity of free fatty acids in oily seeds increases very much during germination, and the only satisfactory explanation of this fact which can at present be offered is that it is the result of the decomposition of the fats, in the manner indicated above, by an unorganized ferment. Again, it was mentioned above that crystallizable nitrogenous organic substances, such as leucin, asparagin, and tyrosin, occur in plants, and it was pointed out that they may be formed synthetically. But there can be no doubt that they may be, and frequently are, formed analytically,—that is, by the decomposition of more

complex substances. For instance, when the seeds of leguminous plants, such as the Pea or the Bean, germinate, the quantity of proteid substance diminishes, and the quantity of amides, notably asparagin, increases; there can be no doubt that the latter are derived from the former. It is well known that similar changes take place in the pancreatic digestion of animals, that leucin and tyrosin are formed from proteids, and that this is effected by an unorganized ferment termed "trypsin"; it is quite possible that a ferment of this kind may be present in plants. Finally, there is probably, in certain plants at least, a ferment which converts cellulose into sugar. For instance, the Date seed contains a quantity of non-nitrogenous reserve material stored up as cellulose in its very thick cell-walls; on germination this undergoes absorption and is conveyed to the embryo; it is extremely probable that the conversion of the insoluble cellulose into some soluble substance (doubtless sugar) is effected by the action of a ferment. The penetration of the absorbent organs of parasites into the tissues of their hosts is probably effected by the action of a ferment of this kind which is excreted by the parasite.

Oxidations.

But there are still other chemical changes to be accounted for as the result of which substances relatively rich in oxygen are produced from others which are relatively poor in that element. Some of these are, so far as is known, processes of simple oxidation, which go on as readily outside the organism as within it; for instance, chlorophyll is oxidized quite as readily in alcoholic solution as when it exists in the chlorophyll-corpuscles of a plant; these processes of simple oxidation may then be regarded as going on independently of the vital activity of the organism. But there are other and more complex oxidations which may be termed "oxidative decompositions"; these involve something more than mere oxidation, and appear to depend upon the vital activity of the organism.

The following instances may be given to illustrate the nature of these changes. Ethyl-alcohol becomes oxidized, under the influence of a Fungus known as the *Mycoderma Aceti*, as follows—

Another similar Fungus, the *Mycoderma Vini*, induces a more complete oxidative decomposition of alcohol,—carbon dioxide and water being the products of its action. Again, a substance termed "pyrocatechin" and various organic acids occur in plants, and there seems reason, from the researches of Hoppe-Seyler and of Carl Kraus, to believe that they are derived from carbohydrates in some such way as the following—

it being understood that this suggests only one of the ways in which the vegetable acids are formed.

Fermentations.

There are yet other processes of decomposition which, like the oxidative decompositions, are effected under the influence of living protoplasm, but which, unlike them, do not depend upon the presence of oxygen; on the contrary, these decompositions, which may be generally termed "fermentations," depend upon the absence of free oxygen, for their activity is the greater the more limited the supply of this element. A characteristic example of this kind is afforded by the decomposition of sugar into alcohol and carbon dioxide, which is effected by Yeast, and is known as the "alcoholic fermentation." Its nature is indicated by the following equation—

Again, various forms of Bacteria effect decompositions of this kind. Of these the putrefaction of organic matter, the lactic and butyric fermentations, are examples. It must not be supposed, however, that the property of exciting fermentation is confined to the protoplasm of lowly plants such as Yeast and Bacteria. It has been found that various fermentations are set up when living plant-organs of any kind—leaves, flowers, fruits, seeds—are kept in an atmosphere which contains no free oxygen.

Respiration

The characteristic accompaniment of the destructive metabolism of plants, as of all living organisms, is, under normal conditions, that interchange of gases between the plant and the atmosphere which is known as "respiration," and which consists in the absorption of oxygen and the

evolution of carbon dioxide. It may be stated generally that the continual absorption of free oxygen is essential to the existence of at least the more highly-organized plants, and that in the absence of a supply of free oxygen they die. Death under these circumstances is to be attributed to the arrest of those metabolic processes which are accompanied by an evolution of kinetic energy in the organism—that is, of the destructively metabolic processes; and of these by far the most important is the self-decomposition of the protoplasm. It would appear that the absorption of oxygen is essential to the self-decomposition of the protoplasm-molecule. It is impossible to say anything definite as to the mode in which oxygen affects this process. Pflüger has, however, suggested that the absorbed oxygen enters into the protoplasm-molecule as "intramolecular" oxygen, that the molecule is thereby rendered unstable, and that it then readily undergoes decomposition.

In contrast to the plants which continue to live only when supplied with free oxygen (the *aerobia*, as Pasteur has termed them) stand the *anaerobia*—those, namely, which thrive best in the absence of free oxygen, and to which, in certain cases, the access of free oxygen is fatal; of the latter, certain Schizomycetes and Saccharomycetes may be taken as examples. It is remarkable that it is just the anaerobic plants which are most highly endowed with the property of exciting fermentation; and this, taken in conjunction with the fact that the activity of fermentation stands in an inverse relation to the supply of free oxygen, indicates the existence of some sort of correlation between the normal respiratory and the fermentative processes. It appears that in aerobiotic plants the normal processes of destructive metabolism, of which the absorption of oxygen and the evolution of carbon dioxide are the outward expression, may be replaced for a longer or shorter time by those abnormal processes of which fermentation is the outward expression; in completely anaerobic plants the fermentative are the normal processes. It is difficult to explain the physiological significance of fermentation, and to determine the manner in which it contributes to the maintenance of the life of the organism. Pasteur has suggested that it is the expression of an effort of the organism to obtain oxygen from substances which contain it in combination. Another possible view is that the organism obtains, by the fermentative decomposition of the substances upon which it acts, the supply of energy which, in the case of an aerobiotic plant, is afforded by the normal decomposition of its own protoplasm-molecules.

The products of destructive metabolism are extremely numerous and of very different chemical nature. They may be roughly classified into two groups: (1) the *waste-products*, substances which cannot be used in the constructive metabolism of the plant, and which may be excreted; and (2) the *plastic products*, substances which can enter into the constructive metabolism.

1. *Waste-Products*.—Among the waste-products the most constant are carbon dioxide and water, which are exhaled in respiration; it may, in fact, be stated generally that all living plants and parts of plants exhale carbon dioxide and watery vapour at all times. There is, however, no constant relation between the volumes of carbon dioxide exhaled and of oxygen absorbed in respiration, and the processes of destructive metabolism, of which the respiratory interchange of gases is the external expression, are so complex that the relation, whatever it may be, between the volumes of these gases in any particular case cannot be accounted for. The degree of independence between these processes is well illustrated by the fact that the absorption of oxygen is relatively greater at low temperatures, and that the exhalation of carbon dioxide is relatively greater at high temperatures. This seems to indicate that at a

low temperature the storing-up of intramolecular oxygen is relatively more active than the decomposition of the protoplasm-molecules, whereas at a high temperature the converse is the case. At medium temperatures these processes are about equally active, for it has been ascertained in various cases that the volumes of oxygen absorbed and of carbon dioxide exhaled are under these circumstances approximately equal. It must not, however, be concluded that the exhalation of carbon dioxide is entirely independent of the absorption of oxygen, for the observations of Broughton, Wilson, and Wortmann all show that when plants are deprived of a supply of free oxygen the activity of the exhalation of carbon dioxide rapidly diminishes.

Among the other waste-products the following are those which are of most common occurrence,—organic acids, aromatic substances, colouring matters, bitter principles, certain fatty bodies, alkaloids.

Organic acids.

(1.) *Organic Acids*.—The organic acids are very generally present in plants, either free or in combination with organic or inorganic bases, and it is to the presence of these acids or of their acid-salts that the acid reaction of plant-tissues is due. Those most commonly occurring are the malic, tartaric, citric, oxalic, and fatty acids, the last-named being generally in combination with glycerin, forming fats (glycerides). There can be little doubt that they are to be regarded as products of destructive metabolic processes, though Liebig regarded some of the more highly-oxidized acids as the first products of constructive metabolism, and as being formed from carbon dioxide and water in the cells which contain chlorophyll. It is not so clear that they are all to be regarded as waste-products; it appears possible that some of the less highly-oxidized may undergo reduction with the formation in carbohydrates, for it has been observed, especially by Beyer, that in ripening fruits the acids diminish and the sugar increases in quantity. Again, there can be no doubt that fats enter into constructive metabolism, and hence the fatty acids must be regarded as plastic products. The more highly-oxidized acids are almost certainly waste-products. Oxalic acid, for instance, is commonly found as crystals of calcium oxalate which, in most cases at any rate, undergo no alteration. It appears that the oxalic acid is withdrawn in this way from the sphere of metabolism, and, inasmuch as these crystals are deposited especially in the deciduous parts of the plant, it is also ultimately got rid of. It is probable that the organic acids are largely produced as the result of oxidative decompositions (see *supra*). There can be no doubt that the self-decomposition of protoplasm is attended by a formation of acids, especially of nitrogenous acids, such as the aspartic and glutaminic, and of fatty acids.

In addition to their significance in the constructive metabolism of plants the organic acids are of use in other ways. Their presence in the living cells contributes to the maintenance of the turgid condition; the presence of acid-sap in the root-hairs renders possible the solution and absorption of mineral substances which are insoluble in water; oxalic acid, at least, decomposes the salts absorbed by the roots; and finally it appears that the organic acids are capable of inducing the conversion of one carbohydrate into another—cane-sugar into glucose, for instance—and they may in this way play an important, though hitherto undetermined, part in the general metabolism of plants.

Aromatic substances.

(2.) *Aromatic Substances*.—These occur generally in the form of glucosides, the most common of which is tannin. The glucosides are bodies, for the most part non-nitrogenous, which yield sugar on decomposition amongst other substances. In so far as they yield sugar they may be regarded as plastic products; but the aromatic substances to which they give rise on decomposition are waste-products, for it appears from the observations which have been made on this point that the higher plants, at least, cannot avail themselves of carbon when combined in an aromatic molecule for the purposes of their constructive metabolism. Probably the resins which are so commonly present in plants are derived from tannin. The first step is the formation of a terpene ($C_{10}H_{16}$) in the secreting cells; this is then excreted into the ducts and undergoes partial oxidation with the formation of resin. In connexion with the terpenes two hydrocarbons, caoutchouc and gutta-percha (C_5H_8)_x, may be mentioned, which occur in the latex of certain plants.

It is not possible to make any definitive statement as to the mode of origin of the aromatic substances in the plant, but the fact that tannin is constantly present in the cells of parts in which destructive metabolism is active—growing points, mobile organs of leaves, galls, for example—tends to prove that this glucoside at least may be derived from protoplasm. It must not be overlooked, too, that substances like tyrosin, which contain an aromatic radical, occur in plants, and that they are derived more or less directly from protoplasm.

(3.) *Colouring Matters*.—The principal colouring matters of Colour-plants are—(a) those which occur in the walls of the bark-cells of trees and shrubs (phlobaphenes); (b) those of woods, such as matters, logwood; (c) those which occur in solution in the cell-sap, as in most flowers; (d) those which occur in connexion with protoplasmic corpuscles, as in the *Algæ* and in the leaves and other green parts of the higher plants. With regard to the three first-named groups it appears probable that they are derived in various ways from tannin.

Of the colouring matters which occur in connexion with protoplasmic corpuscles by far the most important is chlorophyll, the substance to which plants owe their green colour. The corpuscle has a spongy structure, the interstices of which are occupied by the chlorophyll in solution in some fatty substance. The other colouring matters which may be present in corpuscles are—*etioline*, yellow, which is apparently present in all chlorophyll-corpuscles, conspicuously so in those in parts of normally green plants which have been growing in darkness, and is apparently an antecedent of chlorophyll; *xanthophyll*, also yellow, and commonly present in chlorophyll-corpuscles, especially in those of fading leaves, probably a derivative of chlorophyll; *anthoxanthin*, also yellow, the colouring matter of yellow flowers, and a derivative of chlorophyll; *phycoxanthin*, brownish, present in the chlorophyll-corpuscles of the brown *Algæ* (*Phæophyceæ* or *Melanophyceæ*); *phycoerythrin*, red, present in the chlorophyll-corpuscles of the red *Algæ* (*Rhodophyceæ*, *Floridæ*).

Chlorophyll is a substance of such great physiological importance that the conditions of its formation and its properties must be treated of in some detail. The general conditions upon which its formation depends are (a) exposure to light, (b) a sufficiently high temperature, (c) a supply of iron. Plants which are normally green are not green if they have been grown in the dark, or if the temperature has been too low, or if they have not been supplied with iron; they are usually yellow, and in the last case especially they may be quite colourless. Normally green plants which have been kept in the dark or at too low a temperature are said to be “etiolated,” since they form etioline; plants which have grown in absence of a supply of iron are said to be “chlorotic.” There are good grounds for regarding etioline as an antecedent to chlorophyll. It is formed in the corpuscle in darkness and at a temperature lower than that which is necessary for the formation of chlorophyll. It appears from the researches of Iris, Mikosch, and others that when the corpuscle is about to form etioline it contains a starch-granule, and that as it assumes a yellow colour the included starch-granule diminishes in size and may disappear. It must not be inferred from this observation that the etioline is directly formed from the starch. It is more probable that it is derived from the protoplasm, and that, as the protoplasm is consumed in the formation of the etioline, the starch is used in the construction of fresh protoplasm. Under the influence of light and of a sufficiently high temperature the yellow etioline is converted into the green chlorophyll, but nothing is known as to the nature of the process by which the conversion is effected.

With regard to the physical properties of chlorophyll it has long been known that it is soluble in alcohol, ether, benzol, chloroform, carbon disulphide, and various oils. Hansen has obtained, by a process of saponification, from the alcoholic extract of leaves a green crystalline substance, probably the purest form of chlorophyll yet obtained, which is readily soluble in water. All solutions of chlorophyll in the above-mentioned media are fluorescent,—that is, when they are viewed by reflected light they appear opaque and of a deep lake-red colour, but when thin layers are viewed by transmitted light they appear green. If the light which has passed through a layer of a moderately strong solution be examined with the spectroscope a characteristic absorption-spectrum will be observed. Beginning at the red end of the spectrum, a well-marked dark band will be seen between Fraunhofer's lines B and C, extending rather beyond C, a second dark band in the orange between C and D, a third very faint band at the

junction of the yellow and the green, and a fourth more distinct band in the green near F. When an alcoholic extract of leaves is used, as is ordinarily the case, the whole of the blue end of the spectrum beyond F is absorbed, in consequence of the coalescence of three broad bands, which can be seen separately when a very dilute solution is used, two of the bands being in the blue between F and G, and one at the end of the violet. The spectrum of the alcoholic extract presents then seven bands in all. According to Hansen, the spectrum of solutions of his crystallized chlorophyll possesses only the first four of the above-mentioned bands, and it is only when very thick layers are used that the blue end of the spectrum is absorbed; this is true also of the spectrum of the green colouring matter obtained by Tschirch.

Little is as yet known as to the chemical composition of chlorophyll. Gautier and Hoppe-Seyler have both obtained a crystalline green substance from the alcoholic extracts of leaves, termed by the latter "chlorophyllan," which is not to be regarded as pure chlorophyll. The following are their analyses of this substance, to which is added for comparison Hansen's analysis of the green crystalline substance which he obtained—

	Gautier.	Hoppe-Seyler.	Hansen.
C.....	73.97	73.34	60.33
H	9.80	9.72	9.37
N	4.15	5.68	4.77
O	10.33	9.54	14.77
Ash	1.75	{ P. 1.38 } { Mg. 0.34 }	10.76

Hansen states that the ash found by him is due to the previous processes of preparation, and that the only normal ash-constituent is iron, which neither Gautier nor Hoppe-Seyler had discovered. Tschirch on reducing chlorophyllan by means of zinc-dust has obtained a green substance which does not crystallize, and is soluble in alcohol, ether, and oils, but not in water. This he believes to be pure chlorophyll. From the percentage composition of the crystals of chlorophyllan Gautier deduces the formula $C_{19}H_{22}N_2O_3$, and draws attention to the similarity between this and the formula of bilirubin ($C_{16}H_{11}N_2O_3$). Hoppe-Seyler concludes that chlorophyllan contains phosphorus in its molecule, and is either a lecithin or a lecithin compound. Schunck has found that the residue of an ethereal solution of chlorophyll when treated with sulphuric or hydrochloric acid yields glucose amongst other products; he therefore regards chlorophyll as a glucoside.

Bitter principles. (4.) *Bitter Principles.*—It has been ascertained that some of these are glucosides, and some alkaloids, but the chemical nature of many of them is still undetermined. Such are santonin ($C_{16}H_{16}O_3$), aloin ($C_{18}H_{16}O_7$), quasiin ($C_{10}H_{12}O_3$). It is impossible at present to say anything as to the possible mode of their origin or as to their physiological significance in the plant.

Fatty bodies. (5.) *Certain Fatty Bodies.*—The ordinary fats (glycerides) are to be regarded as plastic products, and they will be subsequently treated of under that head. But there are certain fatty bodies of which this statement cannot be made; these are cholesterol, lecithin, and wax. It is not known how these substances are formed, but probably they, like the ordinary fats, are derived from protoplasm. This view is especially probable with regard to lecithin, which is a nitrogenous and phosphorized fat. Wax occurs especially in the external cell-walls or on the surface of those parts of plants which have a cuticularized epidermis; the "bloom" on fruits, for example, is a layer of wax.

Alkaloids. (6.) *Alkaloids.*—The alkaloids are regarded as waste-products, because, as the observations of Knop and Wolff show, the demand for combined nitrogen cannot be met by supplying the plant with it in the form of alkaloids, though the plant can avail itself of such organic nitrogenous substances as urea, uric acid, leucin, tyrosin, or glycocoll. The alkaloids are compound ammonias which are not volatile at ordinary temperatures. With regard to their mode of origin in the plant, there can be little doubt that they are derived more or less directly from protoplasm, or at least from proteid, as are urea and uric acid in the animal body. But, although these nitrogenous waste-products are formed in the destructive metabolism of plants, their formation is not accom-

panied by a loss of nitrogen, for they are not excreted, as is the case in animals, but are deposited in the cells.

2. *Excretion.*—Of the waste-products, some, such as oxygen, water, and carbon dioxide, are excreted in the gaseous form—the oxygen and the carbon dioxide through the superficial cell-walls of the plant, the watery vapour through the stomata. Some of the carbon dioxide may combine with earthy bases to form carbonates, which are either retained in the plant or excreted in solution. The resins and ethereal oils, as well as wax, are frequently excreted. The mechanism of excretion is widely different in different cases. The resins and ethereal oils are usually excreted by means of special glandular organs. The gland may be a hair on the surface, and it is then commonly the terminal cell at the free end which is secretory; or it may be a group of epidermal cells between which large intercellular spaces are formed, which serve as receptacles for the excreted substance; or it may be formed by the absorption of the adjoining walls of a group of cells belonging partly to the epidermis and partly to the underlying ground-tissue, a cavity being thus constructed, which contains the excreted substance; or again, longitudinal strands of cells may become separated so as to enclose an elongated intercellular space into which they excrete (resin-ducts). In many cases the substance to be excreted may be detected in the glandular cells; not unfrequently, however, and always in the case of wax, no trace of it can be discovered in the cells themselves; it is first to be found in the cell-walls between the cuticular and the deeper layers. The actual excretion is usually effected, in the case of superficial glands, by the rupture of the cuticle which is continuous over the gland, and by the consequent escape of the contents; in some cases the gland remains closed, and any volatile substances (ethereal oil) which may be present escape by evaporation.

The excretion of the earthy carbonates in solution is most commonly effected by means of a well-developed gland. Such a gland consists of a group of modified parenchymatous cells in connexion with the termination of a fibro-vascular bundle; and one or two openings, termed "water-pores," and somewhat resembling stomata, are present in the epidermis immediately over it. Under the action of the root-pressure the gland excretes water which holds the carbonates in solution. Glands of this kind are present in the leaves of various Saxifragaceous and Crassulaceous plants. In other cases these salts appear to be excreted by ordinary epidermal cells. In certain Ferns (various species of *Polypodium* and *Aspidium*), for instance, scales of calcium carbonate are found on depressions in the surface of the leaves which are situated immediately over the terminations of the fibro-vascular bundles.

It not unfrequently happens that plants excrete substances other than waste-products, but this has the effect of securing indirect advantages. In the great majority of flowers there are glandular organs which excrete a watery fluid holding principally sugar in solution; these organs are termed "nectaries," and the excretion "nectar." The nectary has essentially the same structure as the water-gland described above, the only important difference being that, whereas the gland is sunk in the tissue and is covered by the epidermis, the nectary has a large free surface, so that the nectar is at once poured out on to the exterior. But there is an important functional difference between them, namely, that, whereas excretion by the gland can only take place under the influence of the root-pressure, excretion by the nectary is independent of the root-pressure, for it will continue when the flower has been removed from the plant. Another instance of an excretion of this kind is afforded by the carnivorous plants. The glands of their leaves excrete a watery liquid which holds in solution a peptic

ferment and one or more organic acids. The use of the nectar is to attract insects, and thus to ensure cross-fertilization. The use of the excretions of the carnivorous plants is to dissolve the organic matter (usually insects) which has been deposited on the leaves, so as to bring it into a form in which it can be absorbed.

Waste-products not excreted. Many of the waste-products are not excreted, but remain in the plant. Thus the terpenes are indeed excreted by the cells which line the resin-ducts, but these ducts have no aperture on the surface of the plant. Similarly the caoutchouc and gutta-percha which are contained in the laticiferous tissue of certain plants have no means of egress. This is also true of the tannic acid, of the calcium carbonate (usually) and oxalate, of the alkaloids, and of silica. These substances are usually deposited in the cells. Calcium carbonate and oxalate are deposited in the form of crystals either in the cell-wall or in the cell-cavity, and silica in the cell-wall. In some cases calcium carbonate is deposited on cellulose processes which extend into the cell from its wall, the whole body being termed a "cystolith."

3. *Plastic Products.*—The principal non-nitrogenous plastic products are the carbohydrates and the fats (glycerides); to these, as suggested above, some of the organic acids are perhaps to be added.

Starch. Of the carbohydrates the substance which most demands attention is starch. Starch makes its appearance in the form of minute granules in chlorophyll-corpuscles in which constructive metabolism is being actively carried on. It was thought that it was the immediate product of the decomposition and recombination of carbon dioxide and of water in the corpuscle under the influence of light, the process being represented by some such equation as the following—

Increased knowledge of the conditions under which starch makes its appearance in plants has, however, made it evident that this is not the case. Starch may be regarded as the first *visible* product of the constructive metabolism going on in a chlorophyll-corpuscle, but it is not the first non-nitrogenous substance formed. That, as has been pointed out, is probably a body allied to formic aldehyde. The starch is formed as one of the products of the decomposition of the protoplasm of the corpuscle. That this is so is made evident when the formation of starch in parts of plants which are not green and which are not exposed to light is considered. In the cells of these parts there are certain small colourless protoplasmic bodies which are termed "starch-forming corpuscles" or "leukoplasts," and it is by these that the starch-granules are formed. It appears that the starch-granule is formed in the first instance by the decomposition of a portion of the protoplasm of the corpuscle, successive layers of starch being deposited upon the primitive granule by the decomposition of successive layers of protoplasm. It is in this way that the stratified structure of these starch-granules is produced. There is no reason for assuming that the process of starch-formation in chlorophyll-corpuscles is essentially different from that in leukoplasts; on the contrary, in view of the close relationship of these bodies, the one being convertible into the other, there is every reason for believing it to be the same. There is, however, this functional difference between chlorophyll-corpuscle and leukoplast, that in the former the synthetic processes, *i.e.*, the construction of protoplasm, begin with such simple substances as carbon dioxide, water, and mineral salts, whereas in the latter they begin (see below) with tolerably complex substances, such, for example, as glucose and asparagin. Starch, then, is the immediate product, not of constructive, but of destructive metabolism.

Glucose. Various kinds of sugar, notably glucose and cane-sugar,

are also commonly to be found in plants. Glucose may be regarded as having been derived by the action of an unorganized ferment from one or other of the other carbohydrates, except in certain plants, the Onion for example, in which it appears to be formed in the chlorophyll-corpuscles in the first instance. Nothing is known at present as to the mode of origin of cane-sugar, which exists in such large quantities in certain plants, as the Beet and the Sugar-cane.

With regard to the fats, it is commonly assumed that Fats. they are formed directly from the carbohydrates, because in oily seeds, for example, as the starch which they contain when young diminishes in quantity it is replaced by fats. There is, however, sufficient evidence to prove that the fats are the products of the decomposition of protoplasm. The disappearance of the starch in ripening oily seeds is due to its being used up in the construction of protoplasm, as the protoplasm undergoes decomposition in connexion with the formation of fat.

The nitrogenous plastic products are proteids and Proteids amides. There can be little doubt that the proteids may be derived from protoplasm. If the molecule of living protoplasm be regarded as an extremely complex one, there is no difficulty in inferring that proteid may be one of the products of the decomposition of the protoplasm-molecule. The amides may also be products of the decomposition of protoplasm, or they may be formed from proteids by the fermentative action of living protoplasm or by the action of some as yet undiscovered unorganized ferment, as pointed out above.

It has been stated that the plastic products are so called because they are substances which can be used in the constructive metabolism of plants. But it must not be inferred that they are so used immediately. The very fact that it is possible to detect their presence in considerable quantity is a proof that this is not the case. They are largely stored up either for the use of the plant itself at some future time, or for the benefit of the progeny of the plant. In a perennial plant, for example, plastic products are stored in the persistent parts for the use of the plant when it recommences its active growth; they are also stored up in seeds and spores to be used by the young plant during the early stages of germination. Plastic products thus stored up are termed "reserve materials," and the organs in which they are deposited are termed "depositories for reserve materials." The non-nitrogenous reserve materials are Non-stored up in the form of carbohydrates or of fats. The nitro-starch which is formed in the green parts of the plant (which is, be it observed, a temporary reserve material) is converted into a soluble substance, probably glucose, and is conveyed in solution to the depository; and from it, directly or indirectly, the non-nitrogenous reserve materials are formed. The reserve carbohydrates are stored up either in the insoluble or the soluble form. In the former case they are deposited as starch-granules, or as cellulose (as in the endosperm of the Date) in thick cell-walls; in the latter they exist as various forms of sugar in solution in the cell-sap. The starch-granules are formed in these depositories by the leukoplasts. From the soluble non-nitrogenous substance, probably glucose, together with nitrogenous substances conveyed to the cells, the leukoplasts construct protoplasm; and it is as the result of the decomposition of this protoplasm in a certain way that starch is formed. This is true also of the reserve cellulose. From the plastic materials, both nitrogenous and non-nitrogenous, which are supplied to the cells protoplasm is constructed, and the external layers of protoplasm undergo decomposition in such a way that cellulose is formed and deposited in successive layers upon the internal surface of the cell-wall. The various kinds of

sugar (cane-sugar in the Beech root, glucose in the Onion, inulin in the Dahlia root, mannite in the unripe fruits of the Olive and in some Agarics, trehalose in many Agarics) are probably formed more or less directly from the glucose conveyed from other parts to the depository in each case. The fats occur as reserve materials characteristically in seeds and sometimes in fruits; they are not stored up in any considerable quantity in any other kind of depository. They too are formed by the decomposition of protoplasm which has been constructed from plastic materials, nitrogenous and non-nitrogenous, which have been conveyed to the cells.

The nitrogenous reserve materials are stored either in solution or as solid granules. In the former case they are amides, such as asparagin and glutamin, leucin and tyrosin, and are held in solution in the cell-sap; they are present characteristically in roots and tubers, but they have also been found, though in small quantity, in seeds. In the latter case these materials are stored in the form of proteids, chiefly globulins and peptones, and the granules in which they are deposited are termed "aleurone grains." The aleurone grain may consist simply of an amorphous mass of proteid, or a portion of the proteid may have crystallized out so as to form a crystalloid; in most cases the grain contains a small mass of mineral matter which consists, according to Pfeffer, of double phosphate of lime and magnesia. Aleurone grains occur characteristically in seeds, and they are especially well developed in oily seeds.

When once deposited, the reserve materials suffer no further change, or at most the proteids may slowly undergo some alteration (globulin being converted into albuminate), so long as the organ in which they are deposited remains in an inactive condition. But when the external conditions become favourable the quiescent organ resumes its active life—in a word, it germinates—and the reserve materials which it contains then undergo chemical changes of such a nature as to convert them into substances which can readily travel to the seat of growth and can be used as plastic material by the growing cells. In a germinating seed, for instance, as the embryo grows the reserve materials of the seed diminish in quantity; they are evidently conveyed to the seedling, and are used by it in the construction of new protoplasm. Beginning with the non-nitrogenous reserve materials, the starch in starchy seeds and the cellulose in such seeds as the Date are converted into sugar; this is proved by the detection of sugar as well in the seed as in the seedling, and by the detection in the seed of an unorganized ferment which possesses the property of converting starch into sugar. In oily seeds the fats are replaced by starch, formed through the intermediation of protoplasm, and the starch so formed is converted into sugar. With regard to the reserve proteids, they are converted into amides, for it has been ascertained that, as they diminish in quantity, the amides, and notably asparagin, increase.

The effect of the absorption of these plastic substances by the embryo is that the cell-sap of its cells becomes charged with them, for the supply is more rapid than the consumption in the formation of protoplasm. If the seedling is growing under favourable conditions these substances gradually diminish in quantity. Some light has been thrown upon the nature of these conditions by the researches of Pfeffer. He found that Lupin seedlings grown in the dark contained a very large quantity of asparagin so long as they continued to live, but that if they were exposed to light the asparagin gradually diminished. But he ascertained further that mere exposure to light is not the cause of this, since the asparagin did not diminish in seedlings exposed to light in an atmosphere which contained no carbon dioxide. The disappearance of the asparagin depended, therefore, upon conditions which were

essential to the formation of non-nitrogenous organic substance by the seedlings. Now the Lupin seed is one which is particularly rich in nitrogenous reserve materials, the quantity of non-nitrogenous reserve materials being relatively small. The accumulation of the asparagin in the seedlings grown in the dark is then to be ascribed to the absence of an adequate supply of non-nitrogenous substance with which it could combine to form proteid. When the seedlings were exposed to light this supply was forthcoming, and then the asparagin disappeared.

Supply of Energy.

It is evident that the various chemical processes which make up the metabolism of plants involve an expenditure of energy; hence of the maintenance of the life of the plant is dependent upon a supply of energy.

In the case of animals the food affords the principal supply of energy. It consists for the most part of complex organic substances which represent a considerable amount of potential energy, and when these substances are decomposed in the body the potential energy appears in the kinetic form. This holds good also with reference to plants which are destitute of chlorophyll, for their food necessarily includes, like that of animals, complex organic substances. But with plants which possess chlorophyll the case is entirely different. Their food consists of inorganic substances which do not represent any considerable amount of potential energy; from these simple substances green plants build up complex organic substances which do represent a considerable amount of potential energy; it is evident, therefore, that green plants must be largely supplied from without with kinetic energy in some form or other. It has been already mentioned that the metabolic processes of plants are materially affected by external conditions, especially by the presence or absence of light, and by variations in the temperature of the surrounding medium. A somewhat elevated temperature is essential to the active life of all plants, but light is essential only to the life of those which contain chlorophyll. This naturally suggests that the energy requisite for the maintenance of the life of plants is obtained by them in the form either of light or of heat.

Light.—In discussing the constructive metabolism of green plants it was pointed out that such can only assimilate their food—that source of energy, can only construct protoplasm from it—when exposed to light, whereas plants which do not possess chlorophyll can assimilate energy their food in the absence of light. It is true that a green seedling can live for a time in continuous darkness and increase in light, but it does so, not by assimilating its food, but at the expense of the organic reserve materials which may be present in it. The fact of the dependence of green plants upon exposure to light suggests that the energy necessary for the processes of their constructive metabolism is obtained in the form of light, and that their chlorophyll enables them to avail themselves of this form of kinetic energy. The function of chlorophyll has been made clear by the researches of Timiriaseff and of Engelmann. They have shown that the evolution of oxygen by a plant containing chlorophyll, which is the expression of the first stages of constructive metabolism, is most active when the plant is exposed to those rays of the solar spectrum which correspond to the absorption-bands of the chlorophyll-spectrum; the more conspicuous the absorption-band, the greater is the degree of activity, so that the evolution of oxygen is most considerable in the rays between the lines B and C of the solar spectrum, at the junction of the red and the orange, which correspond to the absorption-band I in the chlorophyll-spectrum. It is, then, in consequence of this absorption by the chlorophyll that the kinetic energy of the solar rays is made available for the work of constructive metabolism in the plant. The whole of the kinetic energy absorbed by the chlorophyll is not converted into potential energy; still the chlorophyll-corpuscle appears to be a very perfect machine in this respect, for, according to Timiriaseff's calculations, it converts into the potential form as much as 40 per cent. of the absorbed energy. Inasmuch as light exercises so great an influence upon the constructive metabolism of green plants, it may be inferred that it must indirectly affect the absorption of food-materials by the roots. Rudolph Weber has, in fact, ascertained that the greatest absorption of the essential ash-constituents takes place when the plant is kept exposed to those rays of light which are most efficacious in promoting its constructive metabolism.

The effect of light upon the destructive metabolism of plants appears to be unimportant. This subject has been investigated by means of observations upon the respiration of plants; and such a method is calculated to afford the necessary information, inasmuch as the activity of respiration may be taken as a measure of the activity of destructive metabolism.

It has been generally stated that chlorophyll is not formed in the absence of light. There are, nevertheless, certain cases in which its formation in complete darkness has been observed, provided

Nitrogenous reserve materials.

Value of reserve materials for growth.

that the temperature has been sufficiently high, namely, in the cotyledons of some Conifers and in the leaves of Ferns. The colouring matter etiolin is formed in the corpuscles in darkness, but the conversion of this into chlorophyll can only take place, as a rule, under the influence of light. The formation of chlorophyll will take place in light of very low intensity, but, as Wiesner's experiments show, there is a lower limit of intensity below which light is inactive. With regard to the relative efficacy of the different rays of the spectrum in promoting the formation of chlorophyll, it appears from Wiesner's researches that all the rays between Fraunhofer's lines B and H promote it in different degrees, and further, in confirmation of older observations, that seedlings turn green more rapidly in the yellow than in any other part of the spectrum. This last statement is true only for light of moderate intensity; when the light is very intense the formation of chlorophyll takes place more rapidly in blue than in yellow light. The reason of this is that in intense light chlorophyll undergoes decomposition, or at least chemical alteration of the nature of oxidation, which goes on most actively in yellow light.

Heat.—Plants behave in relation to temperature like the cold-blooded animals. When they are maintained at a low temperature they cease to exhibit any signs of life. The meaning of this is that at a low temperature the activity of the metabolic processes is so reduced that they appear to be altogether arrested. But the importance of a moderately high temperature for the maintenance of the active life of the plant is not, as might be supposed, that it affords a continuous supply of energy to be converted into work; it is rather that it determines the initiation of chemical processes which are carried on by means of energy obtained from other sources. Hence the supply of energy in the form of heat is relatively small as compared, on the one hand, with the supply of potential energy afforded by their food to the plants which do not possess chlorophyll, and, on the other hand, with the supply obtained in the form of light by plants which do possess chlorophyll.

It is not possible within the limits of this article to enter fully into the relations existing between plant-life and temperature. The following statements will at least indicate their general nature. In the first place, the tolerance of extreme temperatures is different for different plants, as determined in the case of any particular organ, such as the seeds for instance. Secondly, for each of the processes which can be studied separately, such as germination, growth, respiration, the formation of chlorophyll, the action of unorganized ferments, the evolution of oxygen by green plants in light, &c., there are three cardinal points of temperature to be noted—the *minimum* or *zero point*, at which the performance of the process is just possible; the *optimum point*, at which it is carried on with the greatest activity; the *maximum point*, at which it is arrested. But these different phenomena do not all stand in precisely the same relation to temperature,—that is, the cardinal points for the exhibition of any two or more of these phenomena by one and the same plant do not necessarily coincide. Thirdly, the larger the proportion of water in an organ, the more liable it is to be injured by exposure to extreme temperatures.

Expenditure of Energy.

We have now to ascertain what becomes of energy supplied to the plant. The matter may be briefly stated thus: a portion of it is stored up in the plant in the form of potential energy; the remainder is lost to the plant, being either spent in the performance of mechanical work in connexion with growth or movement, or given off, most generally in the form of heat, occasionally in the form of light, and possibly in the form of electricity. The storing-up of energy in the potential form may be termed the "accumulation of energy," the loss as the "dissipation of energy."

Accumulation of Energy.—The accumulation of energy is the necessary accompaniment of constructive metabolism; the formation of more and more complex organic substances involves the conversion of kinetic into potential energy. By taking into consideration the amount of organic substance formed by a plant from its first development to its death, it is possible to arrive at some idea of the amount of kinetic energy which the plant has stored up in the potential form. For the heat which is given out by burning the organic substance is but the conversion into kinetic energy of the potential energy stored up in the substance; it is but the reappearance of the kinetic energy which was used in producing the substance. The heat, for instance, which is given out by burning wood or coal represents the kinetic energy, derived principally from the sun's rays, by which were effected the processes of constructive metabolism of which the wood or the coal was the product. The amount of energy thus stored up by plants in the potential form is very large, because they produce relatively large quantities of organic substance.

Dissipation of Energy.—The expenditure of energy in connexion with growth and movement, and with the evolution of heat, light, and electricity, is dependent upon destructive metabolism, for the conditions which are essential to destructive metabolism are also those which are essential to the exhibition of these

phenomena. Taking growth, for example—that is, continuous change of form accompanied usually by increase in bulk—it appears that in an aerobiotic plant it is dependent upon the following external conditions, namely, a supply of free oxygen and an adequate temperature, conditions which are precisely those upon which the destructive metabolic processes of such a plant also depend. This is true in such plants of the other above-mentioned phenomena also. Anaerobiotic plants can grow when the conditions are such that they can induce active fermentation,—that is, when their destructive metabolism is active. After what has been said in the section on the "Nervous System" above (p. 38 *sq.*) about animal movement it is hardly necessary to prove that the movements of plants, which are of essentially the same nature as those of animals, depend upon destructive metabolism and involve a dissipation of energy.

An evolution of energy in the form of heat is the inseparable result of destructive metabolism. With regard to plants, it may be stated generally that the evolution of heat is not sufficiently active to raise the temperature of the plant-body above that of the surrounding medium, it being remembered that plants are constantly losing heat, principally by radiation and in connexion with transpiration. In organs, however, in which destructive metabolism is very active it is easy to detect a rise of temperature, especially when a large number of them are collected together. A good instance of this is afforded by germinating seeds; for example, a rise of temperature is a familiar fact in the process of the malting of Barley. It can also be readily observed in the case of opening flowers in dense inflorescences; Warming observed, for example, that, at the time of the opening of the flowers, the inflorescence of an Aroid (*Philodendron bipinnatifidum*) attained a temperature of 18°·5 C. above that of the air.

The evolution of light by plants is a phenomenon which has been known from the times of Aristotle and of Pliny, and is commonly spoken of as "phosphorescence." All the well-authenticated instances of luminosity are confined to the Fungi, to various Agarics, and to Schizomycetes (*Bacteria*). The so-called "phosphorescence" of decaying wood is due to the presence of the mycelium of *Agaricus melleus* (*Rhizomorpha*), and that of putrefying meat and vegetables to micrococci. See PHOSPHORESCENCE. The evolution of light is essentially dependent upon the life of the organism, and further, it is dependent upon the destructive metabolism; for it ceases when the organism is killed (as by dipping it into hot water), or deprived of its supply of free oxygen, which is essential to the metabolic processes.

In view of the changes, both chemical and physical, which are going on with greater or less activity in the various parts of a living plant it has not been unnaturally inferred that the electrical equilibrium is being constantly disturbed, and that differences of electrical potential energy may exist in different parts. Many experimenters have investigated this subject, and such differences have been apparently observed. It is impossible to enter here into a detailed consideration of the results obtained; it may suffice to state that in the majority of cases the electrical currents detected do not indicate a dissipation of the energy of the plant, but are due to physical causes, and in some cases even to the effect upon the organism of the apparatus employed for the purpose of detecting them. It has been clearly made out in certain instances that the currents persist in organs which have been suddenly killed in such a way as not to destroy their gross organization.

There is, however, one instance in which an electrical current has been detected which seems to be connected with the destructive metabolism of the plant. Burdon-Sanderson and Munk have both observed that, when the two electrodes are placed upon a mobile leaf of *Dionaea muscipula* (Venus's Fly-trap) when at rest, a certain electrical current is indicated by the galvanometer. When the leaf is stimulated, whether the stimulation be or be not followed by a movement, the direction of the observed current is suddenly reversed. This change in the direction of the current—or "negative variation," as it is termed—is, according to Burdon-Sanderson, the "visible sign of an unknown molecular process," which he considers to be "an explosive molecular change," of the same nature as the negative variation which follows upon the stimulation of the muscles and nerves of animals.

In concluding this part of the subject it may be well, for the sake of clearness, to draw up an account of the income and expenditure of a plant.

In the case of a plant possessing chlorophyll the income of matter consists of the food (salts, water, carbon dioxide, free oxygen), and the income of energy of kinetic energy in the form of light and heat, the former being the more important of the two items. The great bulk of the food absorbed is converted into organic matter, and is for the most part retained by the plant in the form of organized structures, of reserve materials, and of waste-products which are not excreted; but a certain proportion of it is lost in the form of the carbon dioxide and water exhaled in respiration, of oxygen exhaled by green parts in sunlight, and of excreted organic or inorganic matter. Besides these items of loss there are yet others. All plants lose a certain amount of matter in connexion with repro-

duction, for all plants throw off in the course of their lives certain portions of their structure in the form of seeds, spores, antherozoids, &c. Again, plants which persist for more than one period of growth lose matter by the falling off of certain of their organs and of portions of their structure,—for example, by the falling of the leaves in autumn, and by the shedding of bark, fruits, &c. With reference to the expenditure of energy, a large proportion of the income of energy remains stored up in the potential form in the organic matter which the plant accumulates. A dissipation of energy as heat and in connexion with growth is common to all plants: in some there is dissipation of energy in the form of motion, in some in the form of light, in some, probably, in the form of electricity. A loss of energy—potential energy—occurs also when the plant loses organic matter in any of the ways mentioned above. These various items may be tabulated under the two heads of “income” and “expenditure.” The water lost in transpiration is not considered, for it simply traverses the plant; only that amount of water is considered which may be assumed to enter into the processes of constructive metabolism or to be produced in the processes of destructive metabolism.

Movement of Plants.

Movement. It has been pointed out above that movement, including in the conception the slow movement of growth, is an item in the expenditure of energy by the plant. The phenomena connected with movement are of such physiological importance that it will be well to consider them rather fully.

In dealing with this large subject attention will be directed for the present simply to the external phenomena, leaving the internal causes and mechanisms till subsequently, and those presented by growing organs will be taken first.

1. *Growth.*—In commencing the study of *growth* it is important to have a perfectly clear idea of what the word means. It means the continual change in form of the body of the plant, or of any organ of it, the change being frequently accompanied by increase in bulk, though this is not necessarily the case. For the purposes of this article it will be convenient to use “growth” as meaning, unless expressly stated otherwise, growth in length, that is, the elongation of the organ along the line joining its base and its apex. The conditions upon which growth is dependent are—(1) a supply of plastic material for the formation of new protoplasm; (2) favourable external conditions, especially an adequate temperature; (3) a supply of free oxygen in the case of aerobic plants, or, in the case of anaerobic plants, of fermentable substance; (4) a supply of water to maintain the turgidity of the cells. Any variation in these essential conditions will lead to a variation in the rate of growth. The capacity for growth is limited, as a rule, to a certain period of the life of an organ and of its constituent cells; when this period is past growth ceases, however favourable the external conditions may continue to be.

Rate of growth. The *rate* of growth of an organ is not uniform. At first the organ grows slowly, then more and more rapidly, until a maximum rapidity is reached, and then the rate diminishes until growth ceases altogether. This cycle of spontaneous variation in the rate of growth is known as the “grand period of growth.” It can be conveniently studied by marking on the growing point of an organ a series of transverse zones of known length, and observing their relative elongation in a given time. It will be found that the

youngest (nearest the apex) have elongated slightly, that the elongation is greater the farther each successive zone is from the apex, until a zone of maximum elongation is reached; the elongation of the zones lying behind this will be found to be less and less, until at last zones will be found which have not elongated at all. In addition to the variations in the rate of growth in length of an organ which make up its grand period it is found, if its growth be watched from hour to hour, or at even shorter intervals, that it presents irregular variations, which are likewise to be regarded as spontaneous. Variations in the rate of growth may be induced by variations in the external conditions, especially by variations of temperature and of illumination. It will be of interest to inquire briefly into these relations between growth and temperature and growth and light.

Inasmuch as the decompositions which determine the evolution of energy in the plant are dependent upon temperature, their activity being promoted by a rise of temperature within certain limits, it will be readily understood that growth, which is one expression of the evolution of energy, should likewise be affected by variations in temperature. It has been found, in fact, that the growth of any given plant will only take place within certain limits of temperature, a lowest or minimum temperature on the one hand and a highest or maximum temperature on the other; and further, that between these two points there is one, the optimum temperature, at which the rate of growth is most rapid. Growth is more rapid at each degree as the temperature rises from the minimum to the optimum point; it is less rapid at each degree as the temperature continues to rise from the optimum to the maximum point; and conversely, growth is more rapid at each degree as the temperature falls from the maximum to the optimum, and less rapid at each degree as the temperature further falls from the optimum to the minimum. This dependence of growth on temperature, and this relation between different degrees of temperature and different rates of growth, may be conveniently spoken of as the “tonic influence” of temperature. The mere variation in temperature as such does not appear, as a rule, to affect the rate of growth. Roots exposed to rapid and considerable variations of temperature for some time are found by Pedersen to have grown to about the same extent as similar roots which had been growing for the same time at the mean temperature. The only case in which it appears that variation in temperature produces a distinct effect is afforded by Pfeffer’s observations upon the opening and closing of flowers. He found that a rise of temperature caused the flowers to open and a fall to close, the opening or closing being an expression of the accelerated growth in length of the organ as a whole. This effect of variation of temperature is distinguished as the “stimulating” effect.

In considering the relation of light to growth we have principally to consider its influence as being an essential normal condition and of growth, its “tonic” influence,—that is, it is a question whether or light not light exercises any influence which can be regarded as “stimulating” on the rate of growth. Speaking generally, it may be stated that plant-organs, with the exception of ordinary flattened horizontally expanded leaves and other organs of similar organization, grow at least as well in darkness as in light,—that exposure to light is not an essential condition of their growth. With leaves and leaf-like organs the case is different. When plants are kept for some time in darkness one of the most striking features is the smallness of the leaves of the shoots which have been developed during that time. This is not to be ascribed to an absence of plastic material, for it is exhibited when plastic material is abundantly present in the tissues; nor can it be attributed to the fact that in darkness the leaves are not able to carry on the formation of organic substance, for it is not all leaves which remain small in darkness, but only those which have the organization described above. The long tubular leaves of the Onion, for example, continue to grow in darkness, and so do the long flattened leaves of Irises. The arrest of the growth of flattened horizontally expanded leaves in darkness is due to some peculiar effect, which we must regard as of a “tonic” nature, exercised by light upon the growing cells. Intermittent exposure to light for brief periods suffices to enable the leaves to carry on their growth in darkness, and it is not necessary that the light should be intense. The intermittent exposure induces in the leaf a condition, though it cannot be precisely stated what, which permits of the continuance of growth,—a condition which is termed “phototonus.” Assuming that the organ is actually growing, we find that in all cases light retards the rate of growth, and this the more markedly the greater its intensity. Wiesner has, in fact, shown that growth may be altogether arrested by exposure of the growing organ to intense light. The effect of light in retarding growth has been ascertained by comparative measurements of similar organs growing, some in darkness others in light, and is proved negatively by the greater length usually attained by shoots which have grown in darkness for a given time as compared with that attained in an equal time by shoots growing in light. It appears that variations in the intensity of light, as such, affect the rate of growth. Pfeffer has

found that exposure to light caused certain flowers to open, and to darkness to close. Probably this is accompanied, as in the parallel case of temperature, by an acceleration of the mean rate of growth.

The relation of the long axis of a growing organ to the line of action of gravity appears also to affect its rate of growth. Elfving has found that the sporangiferous hyphæ of *Phycomyces*, which normally grow vertically upwards, grow somewhat less rapidly when they are maintained in the inverse position, that their growth in length is more rapid in opposition to the action of gravity than in the same direction, and this he thinks is true of all organs which normally grow vertically upwards. Gravity would appear, therefore, to exercise a tonic influence on growth. The substitution for gravity of a considerable centrifugal force produced no apparent effect on the rate of growth.

Direction of growth. The direction of growth of an organ is determined partly by inherent and partly by external causes. Beginning with the inherent causes, we find that, when the action of external directive influences upon growing organs is as far as possible eliminated, the axis of growth—that is, the line joining the apex and the base—is approximately a straight line. Thus Vöchting has shown that, when growing shoots are caused to grow in darkness and to rotate slowly about a horizontal axis by means of an instrument termed a “clinostat,” their long axes become straight. This is the expression of an inherent tendency which he terms “rectipetality.” But the line of growth is not at all times straight; for instance, the apex of an organ growing vertically upwards does not travel upwards in a straight line, but oscillates from side to side of the vertical. This oscillation is termed “nutation,” and is due to the fact that growth in length is not uniformly rapid on all sides of the growing organ, but that during any given period of time one side grows more rapidly than the others. This unequal growth, which we may term “heterauxesis,” is apparently spontaneous. The particular path which the apex of an organ describes in the course of its growth depends upon the properties of the organ, a point which may now be conveniently dealt with.

Properties of growing organs. Some information as to the properties of an organ may be obtained from observation of its anatomical structure. For instance, cylindrical organs, such as many shoots, are radially symmetrical in structure, and they are in most cases found to be also physiologically radial. Some organs, again, such as the leaves of some Irises, are bilaterally symmetrical in structure, and they are found to be physiologically bilateral. Other organs, finally, such as flattened expanded leaves, prothallia of Ferns, thalloid shoots of Liverworts, though, like the bilateral organs, they present two opposed surfaces, are not bilaterally symmetrical in structure, inasmuch as the tissues in relation with the two surfaces are differently constituted. Such organs are dorsiventral both anatomically and physiologically. The properties of an organ are not, however, always to be inferred from structure. In some cases radial symmetry of structure is accompanied by dorsiventral properties. This is the case, as Sachs has shown, with the shoots of *Tropæolum majus* under certain circumstances.

The question now naturally arises, How are the peculiar properties induced? In some cases they can only be accounted for by regarding them as inherent; this is true of radial organs, of bilateral organs, and to a certain extent of dorsiventral organs. The lateral branches of dicotyledonous trees have, in many cases, been found to possess inherent dorsiventral properties. In other cases, however, dorsiventrality is induced. It has been found by Frank—and his observation has been corroborated by De Vries—that the dorsiventrality of the lateral shoots of Conifers is induced by their relation to gravity. When maintained in a horizontal position during their growth the side which is uppermost becomes the dorsal surface, the other the ventral surface. Again, Sachs has shown that the young shoot of *Tropæolum* is radial, but that if it be exposed to strong unilateral illumination it exhibits dorsiventral properties, the more strongly illuminated side becoming the dorsal surface, and further, that the plane of dorsiventrality may be altered by causing the light to fall on a fresh side of the shoot. A similar case of the induction of dorsiventrality is offered by the thalloid shoot of *Marchantia*. Tracing the development of the shoot from a gemma, we find the gemma to be bilaterally symmetrical in structure and in physiological properties. It falls to the earth with one surface undermost, which becomes the ventral surface, whilst the upper surface becomes the dorsal. That the dorsiventrality is in this case induced by light is proved by the fact that, if an experiment be so arranged that the light falls on the under surface of the gemma, this becomes the dorsal surface, whilst the upper surface becomes the ventral.

The further question now arises, How can the nature of the properties of an organ be determined, if, as has been shown, it cannot always be determined by an examination of the structure? The answer is, that it can be determined by observing the mode of growth of the organ, and especially its response to the action of external directive influences. Thus, the spontaneous heterauxesis of a radial organ is such that each side in turn is the one which is growing with the greatest rapidity, so that, seen from above, the

apex will appear to describe a somewhat circular orbit, and its path upwards will be spiral. This kind of nutation is termed “revolving nutation,” or “circumnutation” (Darwin). Similarly, in bilateral organs each of the two sides grows alternately the more rapidly, so that, seen from above, the apex appears to oscillate from side to side of the vertical, and its path will be a zigzag line. Also in dorsiventral, as in bilateral, organs each of the two sides grows alternately the more rapidly, but the period of alternation is much longer, and may occur only once during the whole period of growth. For instance, the young leaves of Ferns are rolled up upon their internal (dorsal) surfaces; they present what is known as “circinate vernation.” This is due to the fact that at first the lower (ventral) surface of the leaf grows more rapidly than the upper (dorsal); it is only towards the end of the period of growth that the upper surface grows the more rapidly, and then the leaf expands. Special terms have been applied to these phases of growth; when the upper surface of the organ is growing the more rapidly the growth is said to be “epinastic,” when the lower “hyponastic.”

The spontaneous variations in the direction of growth of an organ thus afford some indication of the nature of its organization, but directive this is more clearly shown by its response to the action of external influential influences. These will now be taken in order.

Radiant Energy.—It will be convenient to consider separately the phenomena exhibited by organs of different physiological properties.

Beginning, then, with radial shoot-organs, it is usually found that Helio-when light falls upon one side of such an organ the organ curves tropism so as to direct its apex towards the source of light,—in other words, in radial that it tends to place its long axis parallel to the direction of the organs. incident rays. The effect of the unilateral illumination is to cause heterauxesis of the organ such that the side upon which the light directly falls is the one which grows the most slowly, and therefore becomes concave. Inasmuch as all curvatures induced by light are included under the term “heliotropism,” organs which exhibit the kind of curvature above described may be said to be “positively heliotropic.” As examples of positively heliotropic radial organs may be mentioned radial stems, the multicellular stipes of some Fungi (*Coprinus*, *Claviceps*), the sporangiferous hyphæ of unicellular Fungi (*Mucor*, *Pilobolus*), radial leaves, such as those of the Onion, and, as exceptional cases, some roots (Onion, *Ranunculus aquatilis*). In other cases the effect of unilateral illumination is the reverse of the above: the organ curves so as to direct its apex away from the source of light, though it still tends to place its long axis parallel to the direction of the incident rays. Organs curving in this manner are said to be “negatively heliotropic.” This condition has been frequently observed in roots, and among shoots it is characteristic of the hypocotyl of the Mistletoe. Many cases of negative heliotropism in shoots have been mentioned, particularly the tendrils of *Vitis* and *Ampelopsis*, in which its existence was first detected by Knight; but the apparent negative heliotropism in these cases is probably the expression of something altogether different, as will be subsequently pointed out. There appear to be some well-authenticated cases of a reversal of heliotropic properties in the course of development of certain organs. Hofmeister states that the floral peduncles of *Linaria Cymbalaria* are positively heliotropic, but that when the fruit has replaced the flower the peduncle is negatively heliotropic; and Wiesner states that the peduncle of *Helianthemum vulgare* is negatively heliotropic after fertilization has taken place. The nature of the heliotropic properties appears thus to vary with the biological conditions of the organs.

When organs are exposed throughout the whole period of their growth to unilateral illumination they usually take up a certain position which is termed the “fixed-light position,” such that they curve towards the direction of incidence of the brightest light. In some cases this is not so. This may be explained by an absence of heliotropic sensitiveness, but in some cases it is due to the fact that the organs follow the daily course of the sun. Wiesner mentions *Sonchus oleraceus* as a striking example of the latter condition. The activity of the curvature stands in a direct relation to the intensity of the incident light. The same botanist has found that for the organs of each plant there is an optimum intensity of light which produces the maximum of heliotropic effect, and that any increase or diminution of this intensity is followed by a diminished heliotropic effect.

With regard to the relative heliotropic effect of rays of different wave-length, it has long been known that the rays of high refrangibility are much more powerful than those of low refrangibility. Wiesner finds the distribution of heliotropic effect in the spectrum to be more exactly this: the greatest curvature is produced by the rays at the junction of the ultra-violet and violet; from this point the heliotropic effect diminishes until, in the yellow, it disappears; it begins to manifest itself again in the orange, and increases until it reaches a small secondary maximum in the ultra-red. Heliotropic effect is by no means confined to the luminous rays of the spectrum. Wiesner, and more recently Wortmann and Barthélemy, have shown that the dark heat-rays possess it. The curva-

tures produced by the dark rays are sometimes designated by the term "thermotropism."

The effect of unilateral illumination is not immediately exhibited, nor does it cease immediately upon the withdrawal of the organ from light. If an organ be exposed for only a short time to unilateral illumination, it may not exhibit any curvature during the period of exposure, but will curve subsequently in darkness. The exposure had sufficed to induce heliotropic curvature. This Wiesner terms "photo-mechanical induction," but it is simply due to the slow response of the organ to the directive influence of the incident rays,—to a long "latent period."

Turning now to the part played by the growing organ in heliotropic curvature, it is clear that the curvature will largely depend upon the heliotropic sensitiveness of the organ, and it must be borne in mind that organs vary widely in this respect. The curvature is in all cases confined to the growing region of the organ, or, to put it more generally, to the region which is capable of growing. In connexion with this point, the further one naturally arises as to the seat of heliotropic sensitiveness. It is usually assumed that those zones which are growing most rapidly are those which are most sensitive, but Darwin found that in some cases (cotyledons of *Phalaris* and *Avena*, hypocotyls of Cabbage and Beet) illumination of the tip of the organ appeared to induce heliotropic curvature. This cannot at present be regarded as fully established.

With regard to the heliotropic phenomena presented by simply bilateral organs, such as the leaves of Irises, it will suffice to say that they are positively heliotropic.

Heliotropism in dorsiventral organs. The heliotropic phenomena presented by dorsiventral organs are more complicated. It has been observed that dorsiventral branches (including the tendrils of *Vitis* and *Ampelopsis* mentioned above), when exposed to vertical light, tend to assume a horizontal position, whereas in darkness they usually grow erect. Dorsiventral leaves usually remain horizontal in darkness. A full discussion of these facts cannot be entered upon here; a few remarks must suffice. It is argued by some, especially by De Vries, that the horizontal position of dorsiventral organs when exposed to light is due to negative heliotropism; but there is no adequate proof that this is really the case. Sachs says on the subject, "So far as I can apprehend the facts, the negative heliotropism of the *Marchantia*-shoot, and that of many other shoots which behave in the same way, is the same phenomenon as the epinasty of foliage-leaves described by De Vries." Detmer has in fact found that exposure to light, quite independently of the direction of the incident rays, induces the rapid growth of the dorsal surface of dorsiventral leaves—in a word, induces photo-epinasty. Continued photo-epinasty would clearly cause the organ to curve downwards below the horizontal plane, and this is occasionally actually the case. But more frequently the organ remains in the horizontal plane when the light falls vertically upon it, or, to put the case more generally, the organ takes up such a fixed-light position that its long axis is at right angles to the direction of the incident rays. Moreover, it has been ascertained that it is always the dorsal surface of leaves which is directed towards the brightest incident light. It is clear that, in addition to the induction of photo-epinasty, light exercises a directive influence upon the growth of these organs. The attempt has been made to explain this by ascribing to the dorsiventral organs merely the heliotropic properties which belong to radial organs, but this explanation is quite insufficient. They can only be accounted for by attributing to dorsiventral organs, as Frank has done, a peculiar heliotropic sensitiveness, which he terms "transverse heliotropism" and Darwin "diabeliotropism," which manifests itself in the assumption of such a position that the dorsal surface of the organ is placed at right angles to the direction of the incident rays.

Gravity.—The influence of gravity in determining the direction of growth of an organ manifests itself in phenomena which are designated by the term "geotropism." We will again consider separately the phenomena which are presented by organs of different physiological properties.

Geotropism of radial organs. Beginning with radial organs, we find that a great number of them normally grow either upwards or downwards; thus, primary shoots grow upwards and primary roots grow downwards. If any attempt is made to alter the direction of growth of these organs they at once curve so as to regain their normal direction. That the direction of growth is actually the result of the action of gravity was first demonstrated by Knight. He caused seeds to germinate on a wheel revolving with sufficient rapidity to set up a considerable centrifugal force, and he found that the roots and stems of the seedlings behaved with regard to the direction of the centrifugal force precisely as they do with regard to that of gravity: the roots grew radially outwards, and the stems radially inwards. He states his conclusion thus: "I conceive myself to have proved that the radicles of germinating seeds are made to descend, and their plumules to ascend, by some external cause, and not by any power inherent in vegetable life; and I see little reason to doubt that gravitation is the principal, if not the only, agent employed in this case by Nature."

In conformity with the terminology used with reference to heliotropism, organs which grow towards the centre of the earth are said to be "positively geotropic" and those growing in the opposite direction "negatively geotropic." As examples of positively geotropic radial organs may be mentioned, in addition to primary roots, the hyphæ of Moulds which penetrate into the substratum, the root-like filaments of *Vaucheria*, *Caulerpa*, and other *Algae*, the rhizoids of *Muscinæ*, the rhizomes of some plants, such as *Yucca* and *Cordyline*. As examples of negatively geotropic radial organs may be mentioned, in addition to primary shoots, the stipes of Mushrooms, the sporangiferous hyphæ of Moulds, the stalks of the receptacles of Liverworts, the setæ of *Muscinæ*, the peduncles of many flowers, the climbing roots of various epiphytes. Cases of the absence of geotropic irritability are afforded by the hypocotyl of the Mistletoe, and by the aerial roots of various epiphytes. A reverse of its geotropic properties may take place in the course of the development of an organ. Vöchting has found, for instance, that the peduncle of the Poppy is negatively geotropic whilst the flower is in the bud, but positively geotropic during flowering and fruiting.

In dealing with these phenomena we have first to consider the effect of gravity acting at different angles. Sachs concludes, and his conclusion is generally accepted, that the geotropic influence of gravity is greatest when the long axis of the organ is at right angles to the vertical, and that it is zero when the long axis of the organ coincides with the vertical, whether the apex point upwards or downwards, or whether the organ be positively or negatively geotropic,—that is, if the force of gravity acting at any point of an organ be decomposed into two forces, the one acting at right angles to the long axis of the organ and the other along it, it is only the former which produces a geotropic effect. Sachs bases this view upon the fact that geotropic curvature is more rapidly produced when an organ is horizontal than when it is in any other position. Elfving has made observations which suggest a different view, namely, that the geotropic action of gravity upon an organ is greatest when that organ is removed as far as possible from its normal relation to the vertical.

The degree of geotropic sensitiveness is different in different organs. This is shown by the different directions of growth taken by different organs when grown under conditions which prevent to a sufficient extent other directive influences from producing any effect. For instance, primary roots grow vertically downwards, but lateral roots grow more or less nearly horizontally. It has been ascertained, by means of centrifugal force, that lateral roots can be induced to behave like primary roots if only the force is sufficient: lateral roots grow radially outwards on the wheel when the centrifugal force is $4g$ (g =force of gravity). It may be inferred that their geotropic sensitiveness is one-fourth of that of primary roots. The response of an organ to the directive influence of gravity, as in the case of heliotropism, is not immediate, but is preceded by a long latent period. An organ placed horizontally will not begin to curve for some time, and if then placed vertically the curvature will proceed for some time. Geotropic curvature, like heliotropic curvature, is a phenomenon of induced heterauxesis, the result being the assumption by the organ of such a position that gravity ceases to exert any directive influence upon it. Primary shoots and roots, for instance, find the vertical to be their position of rest, whereas lateral branches take up a more or less inclined position. It appears that, generally at least, the most rapidly growing zones of organs are those in which geotropic influence is most active. It has been hitherto generally accepted that the seat of most active curvature was also the seat of geotropic sensitiveness. Darwin recently brought forward the view, based upon the behaviour of roots with their tips cut off, that, in the root at least, the tip is the seat of geotropic sensitiveness. This suggestion has given rise to a number of researches, the results of which are so conflicting that it is impossible at present to come to any definite conclusion on the subject.

With regard to the geotropic properties of simply bilateral organs (leaves of Irises, &c.) it need only be said that they are negatively geotropic.

Coming, finally, to the geotropic phenomena presented by dorsiventral organs, we find that many organs which when growing are exposed to light have a more or less oblique direction of growth, dorsiventral organs are clearly negatively geotropic (examples are afforded organs, by the runners of *Polygonum aviculare*, *Atriplex latifolia*, and others, by radical leaves, and by thalloid shoots of *Marchantia*). But some dorsiventral organs do not grow erect in darkness. Frank mentions the runners of *Fragaria lucida*, lateral branches of Conifers, and many dicotyledonous shrubs and trees as examples. He finds, further, that when these organs are placed otherwise than horizontally they curve until they come to lie in that plane, and, if they are placed in an inverse position so that their normally inferior surface (ventral) is uppermost, they twist on their own axes until the normal relation of their surfaces with respect to the vertical is attained; many leaves also behave in this way. Frank

accounts for these phenomena by ascribing to such dorsiventral organs a peculiar geotropic sensitiveness, which he terms "transverse geotropism," and Darwin "diageotropism." De Vries has severely criticized this assumption. He regards the curvatures of shoots and branches into the horizontal plane as being, to some extent, the expression of the negative geotropism of the stems interfered with by the weight of the leaves, and, to some extent, also the expression of those forms of spontaneous heterauxesis termed epinasty and hyponasty which were alluded to above. Similarly he accounts for the torsions observed by Frank by ascribing them to the unequal twisting moment of the leaves on the two sides of the shoot when in the inverse position. In view of the existence of diaheliotropism, it may be regarded as probable that diageotropism exists also. But at present the case for the latter is not sufficiently made out. More experimental evidence must be forthcoming before the assumption of diageotropism can be regarded as fully justified.

Hydro-tropism. *Moisture.*—It has long been known that roots when brought into the neighbourhood of a moist surface curve towards it. For instance, when seeds are sown in a box of damp sawdust, the bottom of the box being perforated with sufficiently large holes, the roots of the seedlings grow downwards into the sawdust, and ultimately project through the holes. They then no longer grow vertically downwards, but curve so as to apply themselves to the moist surface offered by the bottom of the box. To these phenomena Darwin has applied the term "hydrotropism." Organs which curve in this way are said to be "positively hydrotropic"; but there are also "negatively hydrotropic" organs. Wortmann has observed, for instance, that the sporangiferous hyphae of *Phycomyces* curve away from a moist surface. The phenomena are precisely similar to those of heliotropism and of geotropism. The curvature is in this case also the expression of induced heterauxesis. It takes place in this case also with the greatest activity in the region of most rapid growth. Darwin came to the conclusion that the hydrotropic sensitiveness of roots at least is localized in their tips, a conclusion which, though opposed by Detlefsen and Wiesner, is so far confirmed by Molisch's results that it may be accepted as well founded.

Galvano-tropism. *Electricity.*—Elfvig found that when a root is placed vertically between two electrodes it curves towards the positive electrode,—that is, against the direction of the current. In one case (Cabbage) the curvature was towards the negative electrode. Müller (Hettingen), in repeating Elfvig's experiments, found that the curvature was in all cases such as to tend to place the long axis of the root in the plane of the current, the curvature being towards the negative pole. These phenomena are spoken of as "galvanotropism." Müller found that the curvature was induced when the current traversed only the tip of the root, thus affording apparently another instance of localization of sensitiveness in the tip.

Sub-stratum. *The Substratum.*—Dutrochet long ago observed that the hypocotyl of the Mistletoe, in whatever position the seed may have been placed, assumes such a direction of growth that its long axis is perpendicular to the surface on which the seed has germinated. Sachs has shown, by means of rotation on the clinostat, that this position is assumed both by shoots and roots. It is clear that the substratum exercises a directive influence upon the organs growing either outwards from its surface or inwards into its surface, but the nature of this influence has not yet been investigated. It is certainly not to be ascribed, as Van Tieghem suggested, to the mere mass of the substratum. The effect of a cube of turf or a pot of earth would vanish entirely in comparison with the attraction of the earth,—in other words, with the influence of gravity. The phenomena are designated generally by the term "somatotropism."

Contact. *Contact.*—The effect of contact upon the direction of growth of an organ must be clearly distinguished from the effects of considerable pressure. The latter are of two kinds: in the one case the pressure arrests the growth of that side of the organ which is exposed to it; in the other it excites the organ to active growth, particularly in thickness. Examples of the former effect are so common that they need not be specified; examples of the latter are afforded by the thickening of tendrils and of climbing stems when they have firmly grasped some support. The phenomena now to be considered are such as are induced by slight pressure. Striking instances of this are afforded by tendrils. A very slight touch suffices, in the case of the very sensitive, such as those of *Passiflora gracilis* and of *Sicyos angulatus*, to induce very perceptible curvature, which can be detected, according to Darwin, in half a minute after the touch.

Twining of tendrils. In order to illustrate the subject adequately a brief account will be given here of the more important phenomena connected with the twining of tendrils. Darwin has shown that tendrils are not sensitive during the whole of their existence; speaking generally, they are not sensitive when they are either very young or full grown, and are most sensitive when they are about three-fourths grown. Darwin has also found that their sensitiveness is localized. In most the lower or basal part is either not at all sensitive or is sensitive only to prolonged contact. Most tendrils have their tips

slightly but permanently hooked, and the sensitiveness is localized in the concavity of the hook. In some cases (*Cobaea scandens*, *Cissus discolor*) they are sensitive on all sides; in *Mutisia* the inferior and lateral surfaces are sensitive. As a rule, when in its most sensitive condition the tendril is actively circumnavigating, so that it travels over a large area, and there is considerable probability that it will come into contact with some body around which it can twine. When contact takes place the tendril begins to curve round the support. As it does so new points of the sensitive surface are stimulated, and the curvature increases and extends until the whole of the tendril lying between the original point of contact and the apex is wound in a spiral coil round the support. In some cases this is all that takes place. In the great majority of cases, however, the coiling of the apical portion of the tendril round a support is followed by the spiral coiling of more or less of that portion of the tendril which lies between the original point of contact and the insertion of the tendril upon the stem, provided that this is mechanically possible. The spiral coiling of the basal part of the tendril involves, namely, a considerable shortening, and, if both the stem and the support are immovably fixed, this shortening cannot take place. The turns of the coil are not all in the same direction; they are grouped into two or more spires, separated by short straighter portions, the turns of any two successive spires being in opposite directions. This is a mechanical necessity associated with the spiral coiling of a filament attached at both ends. The spiral coiling of the basal part of the tendril usually begins just below the point of attachment to the support. The coiling of tendrils, like all the curvatures hitherto considered, is a phenomenon of induced heterauxesis. Hence it is that the possibility of the twining of a tendril round a support depends upon the thickness of the support and upon that of the tendril. Most tendrils, inasmuch as they are very thin, can twine round strings, but those which are relatively thick can only twine round a support of some thickness, for there is a mechanical limit to the excess of elongation of the convex over the concave side. The spiral coiling of the untouched portion of the tendril has an especial interest, as it offers a striking illustration of the transmission of a stimulus. It is true that the tendrils of many plants, if they fail to come into contact with a support, likewise coil spirally; but this is a much slower process, and only begins at the time when the tendrils are ceasing to grow and to be sensitive.

Tendrils are not, however, the only organs which are sensitive to contact. Other instances are afforded by the petioles of most leaf-climbers, by shoots, and apparently by roots.

In the case of sensitive shoots Dutrochet observed that the twining stem of *Cuscuta* is sensitive like a tendril. Von Mohl suggested that all climbing stems are sensitive, but both Darwin and De Vries were unable to detect the sensitiveness. This view of Von Mohl has been recently revived by Kohl, who finds that the internodes of climbing stems are sensitive to a long-continued pressure which is insufficient to produce any simply mechanical effect. Darwin found the young internodes of *Lophospermum scandens*, which is not a stem-climber, as also the peduncles of *Maurandia semperflorans*, to be sensitive to touch, and Kerner states that this is also the case with the peduncles of many flowers (Poppy, Anemone, Ranunculus, Tulip).

With regard to roots, Darwin was led to suspect, by observing the behaviour of the radicles of seedlings in their attempts to pass winian over obstacles in the soil, that the tip of the radicle is sensitive to contact, and that the stimulus is transmitted from this, the sensory organ, to the growing zones behind it, in which the necessary curvature is then effected. He made experiments by attaching small objects to one side of the tip of the radicle in various plants, by touching one side of the tip with caustic, and by cutting a thin slice off one side, and found in most cases that the radicle curved away from the touched or injured side, that the curvature is precisely the opposite of that performed by tendrils when touched. The peculiar curving of radicles has been termed the "Darwinian curvature." Darwin's conclusions as to the sensitiveness of the radicle have given rise to considerable discussion. It is clear, in the first place, as he himself showed, that radicles are not perceptibly affected by brief contact or by friction; the contact must be prolonged. Those who dissent from Darwin's view, such as Wiesner, Burgerstein, and Detlefsen, urge that the curvatures induced in his experiments are pathological. It seems probable that this objection is valid. It may be admitted at once in the case of the experiments made by means of slicing the root-tip or touching it with caustic. With regard to the effect of small objects, such as pieces of card, it appears that the curvature of the radicle is due mainly, if not entirely, to the substances used in attaching them. In some cases, for instance, they were attached by a drop of shellac. It has been shown that the mere presence of the drop of shellac is sufficient to induce the Darwinian curvature, and microscopical examination has proved that the part touched by the shellac had died away. Moreover, it is known that a radicle can grow downwards against considerable resistance: it can penetrate into mercury; it can perforate tinfoil without deflexion; Darwin, in fact,

estimates the force of downward growth of the radicle at $\frac{1}{4}$ lb, and its lateral pressure, in particular cases, at 8 and 3 lb respectively. The evidence leads to the conclusion that the Darwinian curvature of roots is not the expression of sensitiveness to contact, but that it is the result of injury of one side of the root.

Combined Effects.—Now that the influences which determine the direction of growth have been individually considered, it is possible to account for the characteristic positions taken up by organs in the course of their development. In dealing with this subject it is convenient, as Sachs suggests, to classify organs, according to their ultimate position, into two groups,—those which, under normal conditions, have their long axes vertical and those which have their long axes more or less inclined to the vertical; the former Sachs terms “orthotropic” organs, the latter “plagiotropic.”

Orthotropic organs. The direction of growth of plant-organs under normal conditions is the expression of the resultant effect of various external directive influences. To illustrate this in the case of orthotropic organs, let us consider the primary shoot and the primary root of a seedling growing under conditions which may be taken as normal. In the case of a shoot growing upwards into the air when light falls vertically upon it, its vertical upward growth is chiefly due to the action of gravity,—that is, it is the expression of the particular degree and quality of the geotropic sensitiveness of the shoot. Since the light is equally intense on all sides of the shoot, it exerts no directive influence. Orthotropism is then mainly due to negative geotropism. That this is so can be readily proved in various ways. For instance, the hypocotyl of the Mistletoe, as mentioned above, is not geotropic at all; hence it cannot be included among either orthotropic or plagiotropic organs, for it may grow vertically or it may grow obliquely, its direction of growth being determined chiefly by its somatotropism. Again, when a normally orthotropic organ is grown in darkness on a clinostat its direction of growth is horizontal. Passing now to the case of primary roots growing in the earth, when the conditions are normal—that is, especially when the earth is uniformly moist around the root—their direction of growth is vertically downwards. This is chiefly due to their strong positive geotropism. Let us suppose, now, that the conditions of growth of these organs are somewhat different from those which we have regarded as normal; let us suppose that the shoot or the root is exposed to lateral light, or that the soil about the root is not equally moist on all sides. In the former case, the action of light will tend to induce heliotropic curvature, but it will depend upon the relative strength of heliotropic and of geotropic sensitiveness whether or not a curvature actually takes place. In the case of most orthotropic shoots a curvature (positive) would take place, thus showing the heliotropic sensitiveness of shoots to be greater than the geotropic, but in some instances it would not take place; in the case of most orthotropic roots no curvature would take place, but in some instances (*Sinapis alba* and others) a curvature (negative) would take place, showing that in most cases the heliotropic sensitiveness of roots is less than their geotropic sensitiveness. The unequal moisture in the soil around the root would cause hydrotropic curvature, inasmuch as the sensitiveness of roots to the influence of moist surfaces is greater than their sensitiveness to gravity.

Plagiotropic organs. We will deal with plagiotropic organs in a similar way. The majority of such are lateral members, as branches, leaves, &c. The direction of growth of a lateral member, certainly of branches of stems and roots and probably also of leaves, is at first determined by its relation to the parent axis. It has been found—by Dutrochet, Sachs, and others—that at their first development the long axes of lateral organs make a definite angle—termed the “proper angle”—with the long axis of the parent organ. Dutrochet thought that the proper angle was in all cases a right angle, that the relation of lateral organ to parent axis was of the nature of somatotropism; but this is a too general statement. The original direction of growth of a lateral organ determined by its proper angle would be maintained, in the absence of internal directive influences, by its rectipetality, but in nature it is affected by light, by gravity, &c. Lateral shoot-branches, for example, are either inherently dorsiventral or they become dorsiventral under the influence of gravity or of unilateral illumination; they are then diaheliotropic, though the manifestation of their diaheliotropism may be interfered with by photo-epinasty; they are usually negatively geotropic. Their direction of growth—that is, the direction of their long axes when mature—is the resultant effect of diaheliotropism and of negative geotropism. In the case of lateral root-branches these are plagiotropic but radial; they grow outwards, slightly inclined downwards below the horizontal; as they grow in the dark,—assuming that the moisture of the soil around them is uniform,—their direction of growth is affected to some extent by their slight positive geotropism. Though their geotropic sensitiveness is slight, their hydrotropic sensitiveness is great, so that their direction of growth is often very much modified by their coming into relation with moist areas of soil.

A complicated case of the action of a number of directive influences is afforded by climbing stems, and it may be worth while to specially consider it. When the stem is young and extends only

a few inches above the ground it appears to be growing almost vertically upwards, but as it elongates the last-formed internodes exhibit well-marked circumnutation. It continues to grow upwards mainly in virtue of its negative geotropism, the direction of its growth being little, if at all, affected by light in consequence of its low degree of heliotropic sensitiveness. If now one of the young growing apical internodes comes into contact with a vertical support it begins to twine around it in virtue of the sensitiveness to permanent though slight pressure which, as mentioned above, these organs possess, the direction of the curvature round the support being also that of circumnutation. The coils formed are nearly horizontal when the support is thick and become more nearly vertical as the support grows thinner; in any case, the steepness of the spire always increases after it is first formed, its diameter is thus diminished, and the stem gains a firm grip of the support. As the stem twines round the support it undergoes torsion around its own axis, so that any one side maintains throughout the same position, whether it be directed inwards, towards the support, or outwards or laterally. The direction of torsion may be either the same as that of coiling or the reverse,—that is, either homodromous or antidromous. The direction of torsion appears to depend principally on the relation between the thickness of the climbing stem and that of the support, and on the smoothness or roughness of the surface of the support; when the support is relatively thin the torsion is homodromous, but when it is relatively thick the torsion is antidromous; with smooth supports, up to a certain limit of thickness, the torsion is homodromous, and with rough supports, down to a certain limit of thinness, the torsion is antidromous; in a word, the direction of torsion is determined by the degree of friction between the climbing stem and the support.

2. Movements.—We pass now to the consideration of movements other than those associated with growth, and we take first movements exhibited by protoplasm. These may be classified into two movement-categories,—(1) those which are performed by naked protoplasm,—ments by protoplasm, that is, which is not enclosed in a cell-wall; (2) those exhibited by protoplasm enclosed in a cell-wall. The movements of naked protoplasm are effected in two ways,—either by the protrusion of portions of the protoplasm, termed “pseudopodia,” or by permanent flagelliform protoplasmic filaments, termed “cilia”; the first kind of movement is known as “amoeboid,” the second as “ciliary” movement. The amoeboid movement is exhibited, though rarely, by isolated cells—for instance, by the zoospores of the *Myxomycetes*—and characteristically by those large aggregates of cells which constitute the plasmodia of this group of Fungi. The pseudopodia are thrown out at first as protrusions of the denser hyaline outer layer of the mass of protoplasm, the ectoplasm, and into this the more watery granular internal protoplasmic substance, the endoplasm, gradually flows. The repeated formation of pseudopodia in any given direction will result in locomotion taking place in that direction. The ciliary movement is characteristic of zoospores and of antherozoids. In some cases the organism, as in the case of *Volvox* and *Pandorina*, passes a large part of its existence in the mobile condition, and then the protoplasm is enclosed within a cell-wall which is perforated by the cilia. The number of cilia may be only one; more commonly in zoospores it is two, and sometimes four; occasionally the cilia are numerous, as in the zoospores of *Vaucheria* and *Oedogonium*; in antherozoids they are usually numerous. The cilia are constantly performing a lashing movement, which causes the organism to move forward and at the same time to rotate on its own axis.

In considering the movements of protoplasm when enclosed within a cell-wall, the typical structure of a plant-cell, as described at the beginning of this section (p. 44), must be borne in mind. In many cells the vacuole is found to be traversed by protoplasmic filaments which extend between one part of the primordial utricle and another. These filaments are continually varying in number, in position, and in size; they are formed and withdrawn in the same manner as the pseudopodia of naked masses of protoplasm. This kind of movement is, in fact, amoeboid movement exhibited by protoplasm enclosed within a cell-wall. In all actively living protoplasm, whether naked or enclosed in a cell-wall, a streaming of the more fluid endoplasm can be observed, the direction and rapidity of the current being clearly shown by the granules which are carried along in it. This is very conspicuous in closed cells (as in leaf-cells of *Vallisneria spiralis* and root-hairs of *Hydrocharis morsus Ranae*) when the whole of the endoplasm rotates in a constant direction.

Movements of Mobile Organs.—With regard now to the movements exhibited by mobile organs, to the “movements of variation” as ment they are sometimes termed,—sometimes they are spontaneous, like variation the protoplasmic movements just considered; in other cases they tion. are only performed in consequence of stimulation: they are induced. Instances of spontaneous movements of variation are, for reasons to be given hereafter, comparatively rare. A case in point is afforded by the Telegraph Plant, *Hedysarum (Desmodium) gyrans*. Under favourable conditions, particularly of temperature, the two lateral leaflets of the trifoliate leaf move upwards and downwards, their

apices describing nearly a circle, a revolution taking from two to five minutes. A familiar example of an induced movement is afforded by the leaves of the Sensitive Plant (*Mimosa pudica*). When a leaf is touched the lateral leaflets close in pairs, folding upwards and forwards, and, if the stimulus be strong enough, the main petiole sinks downwards. The movement of this plant is of special interest, inasmuch as it affords an instance of the transmission of a stimulus. It suffices, namely, to touch the terminal leaflet to cause the closing of the successive pairs of lateral leaflets and the sinking down of the main petiole. Another example of induced movement is afforded by the so-called "sleep" of plants; the leaves of many plants, namely, take up during the night a position different from that which they take up during the day. Taking the Sensitive Plant as an example, during the day its leaflets are widely expanded, and its main petioles are directed obliquely upwards; at night its leaflets are folded together and its main petioles are directed obliquely downwards; it takes up at night, in fact, a position similar to that which is induced by a touch. Excessive illumination tends to induce closing. Other examples are afforded by the mobile stamens of the *Cynareæ* and of *Berberis* and *Mahonia*.

The relation of these movements to external conditions is as follows:—

External conditions of these movements.
 1. *Temperature.*—These movements, like the slow movement of growth, only take place within certain limits of temperature, which, however, vary in different cases. Movements of protoplasm, speaking generally, will only go on at temperatures between 0° and 50° C., and between these limits there is an optimum temperature at which they are most rapid. In the case of movements of variation the lower limit lies considerably higher, from 15° to 20° C. The foregoing illustrates the tonic relation between temperature and movement. Sudden changes of temperature have a stimulating effect. For instance, Dutrochet observed that the protoplasm of the internodal cells of a *Chara* exhibited rotation in water at 7° C., which soon ceased when the plant was placed in water at 32° C.; after some time the movement returned, and was again arrested on replacing the plant in water at 7° C.

2. *Light.*—In most cases of protoplasmic movements light appears to exert no influence; in other cases it exerts a tonic influence. For instance, Engelmann has discovered a form of *Bacterium*, termed by him *Bacterium photometricum*, which is only mobile when exposed to light. Again, organs which exhibit spontaneous movements of variation, like the leaflets of *Hedysarum*, or induced movements, like the leaflets of *Mimosa*, lose their power of movement when kept in darkness for a day or two. Exposure to light, or, as it is termed, the state of "phototonus," is an essential condition of their movement. Bright light tends to arrest movement. For instance, the protrusion of pseudopodia by the plasmodium of *Ethaliium septicum* is less active in light than in darkness. This is well shown in the sleep of plants, alluded to above. The "diurnal position" of the leaves is due to exposure to light, the "nocturnal position" to its absence. This is perhaps most clearly exhibited by the Sensitive Plant. Under the normal alternation of day and night the leaves assume alternately the diurnal and nocturnal positions. If a plant be kept for some time in darkness, at a suitable temperature, it will be found that the leaves exhibit periodic movements of opening and closing. They are, in fact, endowed, like those of the Telegraph Plant, with the power of spontaneous movement, which is arrested when the plant is exposed to light. Variations in the intensity of light act as stimuli. For instance, a sudden variation will cause the closing of the leaves of *Mimosa*. Light also exercises a directive influence on mobile protoplasm in some cases. For instance, when bright light falls obliquely on a plasmodium of *Ethaliium septicum*, it causes it to creep away from the light. Again, the chlorophyll-corpuscles in the cells of leaves exposed to bright light are found to accumulate on those surfaces of the cells which are least exposed, to assume what is termed the position of "apostrophe," a change of position which is due to movements in the protoplasm in which the corpuscles are embedded. Finally, the direction of movement of ciliated zoospores swimming in water is affected by light. When light falls obliquely upon a vessel of water containing zoospores, they place themselves so that their long axes are more or less nearly parallel to the direction of the incident rays, and it is along this line that they move. They may either move towards the incident light or away from it, the direction being apparently determined by the intensity of the light, by the age of the zoospores, and by the amount of oxygen in the water. Protoplasmic masses which respond to the directive action of light are said to be "phototactic."

3. *Other Stimuli.*—It has been mentioned that movements may be induced in the Sensitive Plant by mechanical stimulation, by variations of temperature, and variations in the intensity of light. They may also be induced by electrical and chemical stimuli. The effect of an electrical stimulus on protoplasm exhibiting the amoeboid movement is to cause retraction of the pseudopodia. It arrests also the rotating movement of the protoplasm for a time.

4. *Oxygen.*—The presence of oxygen is an essential condition of movement of any kind, in the case at least of aerobic plants.

It appears that anaerobic plants (*Schizomycetes*) are mobile in the absence of oxygen.

Nature and Mechanism of Movements.—On comparing the state-Conditions which have been made above as to the movements of growing organs and of mature mobile organs, their general similarity essential is at once apparent. The spontaneous movement of growth is to move-comparable to the spontaneous movements of protoplasm and of ment. mobile organs, and the performance of the former is dependent upon the same external conditions as the latter. The reaction to the influence of external agents is the same in many instances; for example, strong light arrests growth, and it arrests also the spontaneous movements of the leaves of *Mimosa* and other plants, and contact stimulates tendrils as it stimulates the leaves of the Sensitive Plant. Again, light exercises a directive influence on the growth of growing organs; it also exercises a directive influence on the movements of zoospores and plasmodia. These considerations lead to the conclusion that the causes of the movements must in all cases be the same.

It has been already pointed out that growth and movement are expressions of the expenditure of energy on the part of the organism, that they are dependent upon the decomposition of some complex substance forming part of, or at least present in, the protoplasm. The conditions which are essential to movement of any kind are, then, these: that the decomposable substance in question is formed and decomposed in sufficient quantity, in other words, that the protoplasm is irritable; that the protoplasm is capable of manifesting by a molecular change, which may be accompanied by a change in external form, the evolution of energy attending the decomposition; and, finally, in the case of protoplasm surrounded by a cell-wall, that the anatomical structure is such as to permit of a movement ensuing upon the change in the protoplasm. It is clear that, if the cell-wall is rigid, no change in the protoplasm can cause a change in form of the cell as a whole.

We may regard spontaneous movement as being due to the Spontaneous decomposition of the decomposable substance whereby taneous the protoplasm undergoes a molecular change. The automatic movement-decomposition not unfrequently takes place, as in the case of the ment. Telegraph Plant, at regular intervals, so that the movement is rhythmic or periodic. Spontaneous movement is most active when a certain favourable combination of external conditions is ensured; any variation in the combination leads to a diminution in the activity, or even to complete arrest, of the movement. External conditions may affect the process either of formation or of decomposition of the decomposable substance. For instance, movements are arrested at a low temperature, most probably because either the formation of the decomposable substance or the necessary explosive decomposition does not take place under such circumstances with sufficient activity. Again, when movement is arrested at a high temperature, or by continuous darkness, it is probably for similar reasons. In this way the tonic effect of external conditions may be accounted for. The stimulating effect of external agents may be accounted for in a similar manner.

Movement, whether spontaneous or induced, is regarded as a phenomenon of *contractility* (see above, p. 13), but we have at present no knowledge of the exact nature of the molecular changes which constitute a contraction. It must be borne in mind not only that protoplasm contracts, but that, after contraction, it returns to its condition of rest. Spontaneous movement is the expression of automatic contraction. External tonic conditions either promote or retard movement, by either promoting or retarding contraction and recovery. Stimuli induce contraction.

The mechanism of the movements of protoplasm-masses appears Mechan-to be as follows. Taking first the case of the amoeboid movement, ism of the protrusion of pseudopodia is due to a molecular change, of the movement of a contraction of the protoplasm, which takes place in the ments. ectoplasm at the spot where the pseudopodium is to be formed, an elevation being gradually produced into which the more fluid endoplasm is, as it were, sucked. The rotating movement of protoplasm appears to depend upon a kind of amoeboid movement taking place constantly in one direction,—to be, that is, a creeping movement. Ciliary movement appears to depend on the alternate contraction of each longitudinal half of the cilium. It is not possible at present to attempt any explanation of the directive influence of light on moving protoplasm, but the fact itself is of great physiological importance.

The mechanism of the movements of organs, whether unicellular or multicellular, in which the cell-wall has to be considered is more complicated. The cells possess the structure described above: they consist of a cell-wall lined by the protoplasmic primordial utricle enclosing the cell-sap. They are, moreover, in a state of turgidity,—that is, they are tensely filled with water. The state of turgidity in a cell depends upon three conditions,—(1) upon a tendency to absorb more water in consequence of the presence of osmotically active substances dissolved in the cell-sap; (2) upon the resistance offered by the primordial utricle to the escape of water from the cell; (3) upon the elasticity of the cell-wall. The elasticity of the primordial utricle is so small that it may be

neglected. The growth in length of a filament of *Vaucheria* may be taken as a case illustrative of the importance of turgidity as a condition of growth in unicellular organs. This growth cannot be attributed to a greater hydrostatic pressure at the apex of the cell, for the pressure is necessarily the same at all points, and clearly it cannot be referred to a diminished resistance on the part of the primordial utricle to the passage outwards of water at that point. It must be referred to the cell-wall, and it can only be accounted for on the assumption that the elasticity of the cell-wall is less at the apex than at any other point of its surface.

Growth is not, however, to be regarded as the result merely of the mechanical expansion of the cell which is rendered permanent. There is every reason to believe that the protoplasm takes an active part in producing this expansion, and in determining the direction in which expansion shall more particularly take place. The arrest of growth by strong light is a case in point. There is no reason to believe that this is to be ascribed to an increased rigidity of the cell-wall, or to a diminution of the attraction of the cell-sap for water. It can only be ascribed to a molecular change in the protoplasm, which causes it to offer considerable resistance to any change of form, either spontaneous or such as is induced by the hydrostatic pressure. The arrest of growth which, as we have seen, usually occurs when leaves are kept in continuous darkness is another case in point. The arrest of growth of the cells under these circumstances cannot be referred to a change in the physical properties of either the cell-wall or the cell-sap, but must be attributed to a change in the molecular condition of the protoplasm.

Heter-
auxesis.

The phenomena of heterauxesis, spontaneous and induced, have now to be considered. It will be convenient to deal with induced heterauxesis first, and we will begin with the case of a unicellular organ. It has been mentioned that heterauxesis, in the form of curvature, is induced by the action of light, gravity, &c. Inasmuch as the hydrostatic pressure is necessarily the same at all points of the internal surface of the cell, the curvature must depend upon a local variation of the properties either of the cell-wall or of the protoplasm. In the case of the cell-wall either its rigidity is increased on one side, the concave, or its extensibility increased on the other, the convex. It is just conceivable, with regard to the action of light, that such a difference in properties might be induced by the more direct exposure of one side of a delicate filament to light, though the difference of intensity on the two sides would be very small. But it is not at all conceivable that such a difference could be induced by the action of gravity, and no explanation can be regarded as satisfactory which fails to meet all cases of curvature. The cause of the curvature is doubtless to be sought in the protoplasm. Unilateral illumination of the organ, or an abnormal relation to the line of action of gravity, acts as a stimulus on the organ and causes an alteration in the properties of its protoplasm, which is perhaps of such a nature that it becomes relatively rigid on the side which becomes concave. The induced heterauxesis of multicellular organs is certainly of essentially the

same nature as that of unicellular organs. Applying the above explanation of the curvature of unicellular organs to multicellular organs, the conclusion to be drawn would be that the curvature of the latter is due to the induction of the same changes in the protoplasm in each of their growing cells.

The phenomenon of spontaneous heterauxesis, as exhibited in nutation, may be accounted for in precisely the same way, but it is possible to imagine that it may be due to some extent in the case of unicellular organs to local variations in the extensibility of the cell-wall, and in that of multicellular organs to variations in the extensibility of the cell-walls of groups of cells on different sides of the organ.

The phenomenon exhibited by mature mobile organs, such as the leaves of the Sensitive Plant, &c., remains finally to be considered. The movement of the leaf as a whole is effected by a group of cells, *pulvinus*, constituting a swelling, the *pulvinus*, at the insertion of the main petiole, and of each leaflet by a similar organ at its attachment to the main petiole. The structure of the *pulvinus* is briefly a mass of parenchymatous cells having the same structure as that described above, traversed by a strand of flexible fibro-vascular tissue. When the leaf is fully expanded, its position is maintained by an equality between the downward pressure of the portion of the *pulvinus* above the fibro-vascular strand and the upward pressure of the portion below it. The downward movement of the leaf as a whole is due to a sudden diminution of the upward pressure of the lower portion of the main *pulvinus*; similarly, the upward movement of a leaflet is due to the sudden diminution of the downward pressure of the upper portion of its *pulvinus*. In both cases the diminution of pressure is due to a loss of turgidity of the portion of the *pulvinus* concerned: the cells become flaccid. This loss of turgidity has been shown to be due to an escape of water from the cells, which can only be accounted for by ascribing it to a change in the molecular condition of their protoplasm. In spontaneous movements this change is induced automatically, in induced movements by the action of a stimulus. This molecular change is probably of such a kind that the protoplasm takes up water into itself, and at the same time allows it to pass through. The recovery of turgidity is slow. The arrest of movement which is induced by long-continued darkness or by exposure to light is probably due to the prevention of the occurrence of molecular change in the protoplasm. The conduction of a stimulus, which undoubtedly takes place in the leaves of the Sensitive Plant, and probably in many other plant-organs (see above on heliotropism, geotropism, hydrotropism, tendrils), is effected by means of the delicate filaments of protoplasm which, as Gardner has clearly shown in the *pulvinus*, are continuous between the protoplasm-bodies of adjacent cells.

For the reproduction of plants, see REPRODUCTION.

Literature.—The following works on the physiology of plants may be consulted.—Sachs, *Lehrbuch* (2d Eng. ed., Oxford, 1882) and *Vorlesungen über Pflanzenphysiologie* (Leipzig, 1882); Pfeffer, *Pflanzenphysiologie* (Leipzig, 1881); Van Tieghem, *Traité de Botanique* (Paris, 1884); Darwin, *Climbing Plants* (1875) and *The Power of Movement in Plants* (1880). PIACENZA (Fr., *Plaisance*; Lat., *Placentia*), a city of Italy, a bishop's see, and the chief town of a province, lies on the Lombard plain, 217 feet above sea-level, not far from the right bank of the Po, just below the confluence of the Trebbia. By rail it is 43 miles south-east of Milan and 35½ north-west of Parma. Formerly a place of considerable strength, it is still surrounded by walls with bastions and fosse in a circuit of 4 miles. The cathedral was erected between 1122 and 1233, in the Lombardo-Gothic style, under the direction of Santo da Sambuceto, on the site of a church of the 9th century which had been destroyed by earthquake. The west front has three doors with curious pillared porches. The campanile is a massive square brick tower 223 feet high; the iron cage attached to one of its windows was put up in 1495 by Ludovico il Moro for the confinement of persons guilty of treason or sacrilege. The crypt is a large church supported by one hundred columns. Sant' Antonino, which was the cathedral church till 877, and occupies the spot where it was reputed that St Barnabas preached to the people, was built by St Victor, the first bishop of Piacenza, in 324, restored in 903, rebuilt in 1104, and altered in 1857. It was within its walls that the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. The brick vestibule (Il Paradiso) on the north side is one of the older parts of the building. San Francesco, a spacious edifice begun by the Franciscans in 1278, occupies the site of Ubertino Landi's palazzo, and is famous as the place where Agostino Landi harangued the people after the murder of Pierluigi, and where in 1848 the deputies of Piacenza proclaimed the annexation of their city to the Sardinian kingdom. San Sisto, which dates from 1499, and takes the place of the church founded in 874 by Angilberga (consort of the emperor Louis II.) for the Benedictines, lost its chief attraction when Raphael's Sistine Madonna (now in Dresden) was sold by the monks in 1754 to Frederick Augustus III. San Sepolcro and Sta Maria della Campagna are both after Bramante's designs; the latter is rich in works of Pordenone. Sant' Anna, dating from 1334, was the church of the barefooted Carmelites. Of the secular buildings in the city the most interesting is the Palazzo Comunale, begun in 1281. In the main front the lower story, constructed of red and white marble, presents a series of five open pointed arcades; the upper story, in brick, has six very rich round-arched windows, each of five lights; and above the cornice rise forked battlements. The square in front is known as the Piazza dei Cavalli, from the two bronze equestrian statues of Ranuccio (1620) and his father Alexander, prince of Parma, governor of the Netherlands (1625). Both were designed by Francesco Mocchi. The Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558; but it was never completed, and since 1800 it has been used as barracks. Other buildings or institutions of

note are the old and the new bishop's palace, the fine theatre designed by Lotario Tomba in 1803, the great hospital dating from 1471, the library presented to the commune in 1846 by the marquis Ferdinando Landi, and the Passerini library founded in 1685. About a mile to the east of the city is the Collegio Alberoni, instituted in 1751 for the education of priests and missionaries. At a distance of about 2 miles in the opposite direction the Trebbia is crossed by a bridge of twenty-three arches, erected in 1825 at a cost of £47,000; the Austrians blew up two of the arches in 1859. Piacenza is an important point in the Italian railway system—the Lombardy, Piedmont, and Ligurian lines meeting there with those of Central Italy. Silk, cotton, and woollen goods, pottery, and hats are among the local manufactures. The population of the commune (which in this case is almost exactly identical with the city) was 34,985 in 1871 and 34,987 in 1881.

Piacenza, originally, it is supposed, a Ligurian and afterwards a Gallic town, was made a Roman colony in 219 B.C. While its walls were yet unfinished it had to repulse an attack by the Gauls, whose hopes were excited by the news of Hannibal's approach, and in the latter part of 218 it afforded protection to the remains of the Roman army under Scipio which had been defeated by the Carthaginian general in the great battle on the Trebbia. In 207 it withstood a protracted siege by Hasdrubal, Hannibal's brother, and thus contributed largely to the ultimate success of the Romans. Seven years later the Gauls surprised and burned the city; and the colony was so diminished in strength that in 190 it had to be recruited with three thousand families. In 187 it was connected with Rimini and the south by the construction of the Æmilian Way. During the later republic and the empire Placentia is named in connexion with a defeat of the forces of Marius in the neighbourhood (82 B.C.), a mutiny of Julius Cæsar's garrison (49 B.C.), another mutiny under Augustus (41 B.C.), the defence of the city by Spurius, Otho's general, against Cæcina, Vitellius's general (69 A.D.), and the defeat of Aurelianus by the Marcomanni outside the walls (271 A.D.). In 546 Totila reduced Piacenza by famine. Between 997 and 1035 the city was governed by its bishops, who had received the title of count from Otho III. In the latter part of the 12th century it was one of the leading members of the Lombard League. For the most part it remained Guelph, though at times, as when it called in Galeazzo Visconti, it was glad to appeal to a powerful Ghibelline for aid against its domestic tyrants. In 1447 the city was captured and sacked by Francesco Sforza. Having placed itself directly under papal protection in 1512, it was in 1545 united with PARMA (*q.v.*) to form an hereditary duchy for Pierluigi Farnese, son of Paul III. In 1746 a battle between the Franco-Spanish forces and the Austrians was fought under the city walls. In 1848 Piacenza was the first of the towns of Lombardy to join Piedmont; but it was re-occupied by the Austrians and had to wait for its emancipation till 1859. Lucius Calpurnius Piso (father-in-law of Julius Cæsar), Pope Gregory X., and Alexander Farnese, duke of Parma, were natives of the city. Among the local historians are Boselli, Rossi, Bonara, and Gemmi.

PIANOFORTE. The group of keyed stringed instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music, which is based upon the simultaneous employment of different musical sounds. In the

10th century the "organum" arose, an elementary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it; and the organ, the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. There was as yet no keyboard of balanced key levers; batons were drawn out like modern draw-stops, to admit the compressed air necessary to make the pipes sound. About the same time arose a large stringed instrument, the organistrum, the parent of the now vulgar hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St George de Boscherville, one string was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum. In the 11th century, the epoch of Guido d'Arezzo, to whom the beginning of musical notation is attributed, the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely to demonstrate the proportionate relations of the intervals, but also to initiate pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex-fashioned monochords, which were constructed with scales, analogous to the modern practice with thermometers which are made to show both Réaumur and Centigrade, so that four lines indicated as many authentic and as many plagal tones. This arrangement found great acceptance, for Aribo, writing about fifty years after Guido, says that few monochords were to be found without it. Had the clavichord then been known, this make-shift contrivance would not have been used. Aribo strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a wild-goat (*caprea*). Jean de Muris (*Musica Speculativa*, 1323) teaches how true relations may be found by a single-string monochord, but recommends a four-stringed one, properly a tetrachord, to gain a knowledge of unfamiliar intervals. He describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St Mary's Church, Shrewsbury. The latest date to which this interesting figure may be attributed is 1460, but the conventional representation shows that the instrument was then already of a past fashion, although perhaps still retained in use and familiar to the carver.

A keyboard of balanced keys may have been first introduced in the little portable organ known as the regal so

often represented in old carvings, paintings, and stained windows. It derived its name regal from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Athole, and it bears the very late date of 1630. The Brussels regal may be as modern. These are instances of how long a some-time admired musical instrument may remain in use after its first intention is forgotten. We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents fixed in the further ends of the balanced keys for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. This use of the word to imply gradation was common in England to all keyed instruments; thus we read, in the Tudor period and later, of a pair of regals, organs, or virginals.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna. The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicymbalum, the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite mediæval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer. There were two forms of the psaltery:—(1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically,—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but, according to Mersenne, the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicymbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia, which compares in probable date with the Shrewsbury example. We quote the reference to it from Dr Ambros's *History of Music*. He says a carving represents King David as holding an "istromento di porco" which has eight strings and as many keys lying parallel to them; he touches the keys with the right hand and damps the strings with the left. The attribution of archaism applies with equal force to this carving as to the Shrewsbury one, for when the monastery of Certosa was built chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic organs

FIG. 1.—Earliest existing representation of a Keyed Stringed Instrument from St Mary's, Shrewsbury (primitive Clavichord). Before 1460. Drawn by Miss Edith Lloyd.

with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Prætorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und ausgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

FIG. 2.—Diatonic Clavichord Keyboard (Guido's Scale) from Virdung. Before 1511.

The extent of this scale is exactly Guido's. Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass staff to G above the treble. But Virdung tells us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical genera of the Greeks—the diatonic, chromatic, and enharmonic. But the last-named had not been attained. Virdung gives woodcuts of the clavicordium, the virginal, the clavicimbalum, and the claviciterium. We reproduce three of them (figs. 3, 6, and 12), omitting the virginal as obviously incorrect. All these drawings have been continually repeated by writers on musical instruments up to the present day, but without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive Praxis Musicae*, Strasburg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the claviciterium, are transposed, another cause of error. Martin Agricola (*Musica Instrumentalis*, Wittenberg, 1529) has copied Virdung's illustrations with some differences of perspective, and the addition, here and there, of errors of his own.

FIG. 3.—Virdung's Clavicordium, 1511; reversed facsimile.

Still vulgarly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. He derives the clavichord from Guido's monochord as he does the virginal from the psalter, but, at the same time, confesses he does not know when, or by whom, either instrument was invented. We observe in this drawing the short sound-board, which always remained a clavichord peculiarity, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of striking place for the tangents against the strings the keys were made crooked, an expedient further rendered necessary by the "fretting,"—three tangents, according to Virdung, being directed to stop as many notes from each single group of three strings tuned in unison; each tangent thus made a different vibrating length of string. In the drawing the strings are

merely indicated. The German for fret is *Bund*, and such a clavichord, in that language, is known as a "gebunden" one, both fret (to rub) and *Bund* (from *binden*, to bind), having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto," touch. Prætorius, who wrote a hundred years later than Virdung, says two, three, and four tangents were thus employed in stopping. The oldest clavichords extant have no more than two tangents to a note formed by a pair of strings, no longer three. Thus seven pairs of strings suffice for an octave of twelve keys, the open notes being F, G, A, B flat, C, D, E flat, and by an unexplained peculiarity, perhaps derived from some special estimation of the notes which was connected with the church modes, A and D are left throughout free from a second tangent. A corresponding value of these notes is shown by their independence of chromatic alteration in tuning the double Irish harp, as explained by Galilei in his treatise on music, published in 1581. Adlung, who died in 1762, speaks of another fretting, but we think it must have been an adaptation to the modern major scale, the "free" notes being E and B. Clavichords were made with double fretting up to about the year 1700,—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach was now able to produce, in 1722, *Das wohltemperirte Clavier*, the first collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned, as to concordance and dissonance, fairly equal.

The oldest clavichord, here called manicordo (as French, *manicorde*, from monochord), known to exist is that shown in fig. 4. It will be observed that the lowest octave is

FIG. 4.—Manicordo (Clavichord) d'Eleonora di Montalvo, 1659; Kraus Museum, Florence.

here already "bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-board. Mersenne's "manicorde" (*Harmonie Universelle*, 1636), shown in an engraving in that work, has the strings still nearly of equal length, but divides the sound-board bridge into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always form the second

FIG. 5.—Clavichord Tangent.

bridge, indispensable for the vibration, as well as act as the sound exciters (fig. 5). The common damper to all the strings is a list of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately

stopped vibration. Too much cloth would diminish the tone of this already feeble instrument, which gained the name of "dumb spinet" from its use. The cloth is accurately painted in the clavichord Rubens's St Cecilia (Dresden Gallery) plays upon,—interesting as perhaps representing that painter's own instrument. The number of keys there shown is three octaves and a third, F to A,—the same extent as in Handel's clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), but with a combined chromatic and short octave peculiarity in the lowest notes we shall have to refer to when we arrive at the spinet; we pass it by as the only instance in the clavichord we have met with. The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century, before its expressive power, which is of the most tender and intimate quality, could have been, from the nature of the music played, observed,—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin. Holbein, in his drawing of the family of Sir Thomas More, 1528, now at Basel, indicates the place for "Klavikordi und ander Seytinspill." But it remained longest in use in Germany—until even the beginning of the present century. It was the favourite "Klavier" of the Bachs. Besides that of Handel already noticed, there are in existence clavichords the former possession of which is attributed to Mozart and Beethoven. The clavichord was obedient to a peculiarity of touch possible on no other keyboard instrument. This is described by C. P. Emmanuel Bach in his famous essay on playing and accompaniment, entitled *Versuch über die wahre Art das Klavier zu spielen* (An Essay on the True Way to play Keyboard Instruments). It is the "Bebung" (trembling), a vibration in a melody note of the same nature as that frequently employed by violin players to heighten the expressive effect; it was gained by a repeated movement of the fleshy end of the finger while the key was still held down. The "Bebung" was indicated in the notation by dots over the note to be affected by it, perhaps showing how many times the note should be repeated. According to the practice of the Bachs, as handed down to us in the above mentioned essay, great smoothness of touch was required to play the clavichord in tune. As with the monochord, the means taken to produce the sound disturbed the accuracy of the string measurement by increasing tension, so that a key touched too firmly in the clavichord, by unduly raising the string, sharpened the pitch, an error in playing deprecated by C. P. Emmanuel Bach. This answers the assertion which has been made that J. S. Bach could not have been nice about tuning when he played from preference on an instrument of uncertain intonation.

The next instrument described by Virdung is the virginal (*virginalis*, proper for a girl), a parallelogram in shape, with a projecting keyboard and compass of keys the same as the clavichordium. Here we can trace derivation from the psaltery in the sound-board covering the entire inner surface of the instrument and in the triangular disposition of the strings. The latter in Virdung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavicimbalum, this is rectified, and the drawing, reversed on account of the key-board, can be accepted as roughly representing the instrument so called (fig. 6).

There would be no difference between it and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name unnoticed by Virdung or by his countryman

Arnold Schlick, who, in the same year 1511, published his *Spiegel der Orgelmacher* ("Organ-builders' Mirror"), and

FIG. 6.—Virdung's Clavicimbalum (Spinet), 1511; reversed facsimile.

named the clavichordium and clavicimbalum as familiar instruments. In the first place, the keyboard, beginning apparently with B natural, instead of F, makes the clavicimbalum smaller than the virginal, the strings in this arrangement being shorter; in the next place it is almost certain that the Italian spinet compass, beginning apparently upon a semitone, is identical with a "short measure" or "short octave" organ compass, a very old keyboard arrangement, by which the lowest note, representing B, really sounded G, and C sharp in like manner A. The origin of this may be deduced from the psaltery and many representations of the regal, and its object appears to have been to obtain dominant basses for cadences,—harmonious closes having early been sought for as giving pleasure to the ear. We have found a hitherto unnoticed authority for this practice in Mersenne, who, in 1636, expressly describes it as occurring in his own spinet (*espinette*). He says the keyboards of the spinet and organ are the same. Now, in his Latin edition of the same work he renders *espinette* by *clavicimbalum*. We read (*Harmonie Universelle*, Paris, 1636, liv. 3, p. 107)—"Its longest string [his spinet's] is little more than a foot in length between the two bridges. It has only thirty-one steps ["marches"] in its keyboard, and as many strings over its sound-board [he now refers to the illustration], so that there are five keys hidden on account of the perspective,—that is to say, three naturals and two sharps ["*feintes*," same as the Latin *ficti*], of which the first is cut into two [a divided sharp forming two keys]; but these sharps serve to go down to the third and fourth below the first step, C *sol* [tenor clef C], in order to go as far as the third octave, for the eighteen principal steps make but an eighteenth, that is to say, a fourth more than two octaves." The note we call F he, on his engraving, letters as C, indicating the pitch of a spinet of the second size, which the one described is not. The third and fourth, reached by his cut sharp, are consequently the lower A and G; or, to complete, as he says, the third octave, the lowest note might be F, but for that he would want the diatonic semitone B, which his spinet, according to his description, did not possess.¹ Mersenne's statement sufficiently proves, first, the use in spinets as well as in organs of what we now call "short measure," and, secondly, the intention of cut sharps at the lower end of the keyboard to gain lower notes. He speaks of one string only to each note; unlike the double and triple strung clavichord, those instruments, clavicimbalum, spinet, or virginal, derived from the psaltery, could only present one string to the mechanical plectrum which twanged it. As regards the kind of plectra earliest used we have no evidence. The little crow-quill points, Scaliger, who was born in 1484, ex-

¹ Mr A. J. Ellis (*History of Musical Pitch*, p. 318) sees the B in Mersenne's outline diagram.

pressly says were introduced when he was a boy. They project from centred tongues in uprights of wood known as "jacks" (fig. 7), which also carry the dampers. The

FIG. 7.—Spinnet "Jack."

quills, rising by the depression of the keys in front, set the strings vibrating as they pass them,—springs at first of steel, later of bristle, giving energy to the twang and governing their return. Scaliger remembered the "harpichordum" and "clavicimbalum" being without those quill-points (*mucrones*), and attributes the introduction of the name "spinetta" to them (from *spina*, a thorn). We will leave harpichordum for the present, but the early identity of clavicimbalum and spinetta is certainly proved. Scaliger's etymology has remained unquestioned until quite recently; it is due to Signor Ponsicchi of Florence to have discovered another derivation. He has found in a rare book entitled *Conclusione nel suono dell' organo, di D. Adriano Banchieri* (Bologna, 1608), the following passage, which translated reads:—"Spinetta was thus named from the inventor of that oblong form, who was one Maestro Giovanni Spinetti, a Venetian; and I have seen one of those instruments, in the possession of Francesco Stivori, organist of the magnificent community of Montagnana, within which was this inscription—*Joannes Spinetus Venetus fecit, A.D. 1503.*" Scaliger's and Banchieri's statements may be combined, as there is no discrepancy of dates, or we may rely upon whichever seems to us to have the greater authority, always bearing in mind that neither invalidates the other. The introduction of crow-quill points, and adaptation to an oblong case of an instrument previously in a trapeze form, are synchronous; but we must accept 1503 as a late date for one of Spinetti's instruments, seeing that the altered form had already become common, as shown by Virdung, in another country as early as 1511. After this date there are frequent references to spinets in public records and other documents, and we have fortunately the instruments themselves to put in evidence, preserved in public museums and in private collections. The oldest spinet we can point out is in the Conservatoire, Paris. It is a pentagonal instrument made by Francesco di Portalupis at Verona, 1523. The Milanese Rossi were famous spinet-makers, and have been accredited (*La Nobiltà di Milano*, 1595) with an improvement in the form which we believe was the recessing of the keyboard, a feature which had previously entirely projected; by the recessing a greater width was obtained for the sound-board. The spinets by Annibale Rosso at South Kensington, dated respectively 1555 (fig. 8) and 1577,

FIG. 8.—Milanese Spinetta, by Annibale Rosso, 1555; South Kensington Museum.

show this alteration, and may be compared with the older and purer form of one, dated 1568, by Marco Jadra (also known as Marco "dalle spinette," or "dai cembali"). Besides the pentagonal spinet, there was an heptagonal variety; they had neither covers nor stands, and were often withdrawn from decorated cases when required for performance. In other instances, as in the 1577 Rosso spinet, the case of the instrument itself was richly adorned.

The apparent compass of the keyboard, in Italy generally exceeded four octaves by a semitone, E to F; but we may regard the lowest natural key as usually C, and the lowest sharp key as usually D, in these instruments, according to "short measure."

The rectangular spinet, Virdung's "virginal," early assumed in Italy the fashion of the large "cassone" or wedding chests. The oldest we know of in this style, and dated, is the fine specimen belonging to M. Terme which figures in *L'Art Decoratif* (fig. 9). Virginal is not an Italian name; the rectangular instrument in Italy is "spinetta tavola." In England, from Henry VII. to Charles II., all quilled instruments (*stromenti di penna*), without distinction as to form, were known as virginals. It was a common name, equivalent to the contemporary Italian *clavicordo* and Flemish *clavisingel*. From the latter, by apocope, we arrive at the French *clavecin*,—the French *clavier*, a keyboard, being in its turn adopted by the Germans to denote any keyboard stringed instrument.

Mersenne gives three sizes for spinets,—one 2½ feet wide, tuned to the octave of the "ton de chapelle" (in his day a half tone above the present English medium pitch), one of 3½ feet, tuned to the fourth below, and one of 5 feet, tuned to the octave below the first,—the last being therefore tuned in unison to the chapel pitch. He says his own spinet was one of the smallest it was custom-

FIG. 9.—Spinetta Tavola (Virginal), 1568; collection of M. Terme, Liège.

ary to make, but from the lettering of the keys in his drawing it would have been of the second size, or the spinet tuned to the fourth. The octave spinet, of trapeze form, was known in Italy as "ottavina" or "spinetta di serenata." It had a less compass of keys than the larger instrument, being apparently three and two-third octaves, E to C,—which by the "short measure" would be four octaves, C to C. We learn from Prætorius that these little spinets were placed upon the larger ones in performance; their use was to heighten the brilliant effect. In the double rectangular clavisingel of the Netherlands, in which there was a movable octave instrument, we recognize a similar intention. There is a fine spinet of this kind at Nuremberg. Prætorius illustrates the Italian spinet by a form known as the "spinetta traversa," an approach towards the long clavicembalo or harpsichord,—the tuning pins being immediately over the keyboard. This transposed spinet, more powerful than the old trapeze one, became fashionable in England after the Restoration,—Haward, Keene, Slade, Player, Baudin, the Hitchcocks, Mahoon, Hazby, the Harris family, and others having made such "spinnets" during a period for which we have dates from 1664 to 1784. Pepys bought his "Espinette" from Charles Haward for £5, July 13, 1668.

The spinets of Keene and Player, made about 1700, have frequently two cut sharps at the bass end of the key-

board, which Mersenne's short measure, and the realization at that time of the independence of each key in the chromatic scale, may be taken when combined to explain.

FIG. 10.—English Spinet (Spinetta Traversa), by Carolus Haward. About 1668. Collection of Mr W. Dule, London.

Hitherto such cut sharps have been assumed to be quarter tones, but enharmonic intervals in the extreme bass can have no justification. From the tuning of Handel's Italian clavicord already mentioned, which has this peculiarity, and from Prætorius we find the farther halves of the two cut sharps were the chromatic semitones, and the nearer halves the major thirds below what they appeared to be. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals. Their instruments, always numbered, and not dated as has been sometimes supposed, became models for the contemporary and subsequent English makers.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della Musica Antica e Moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp,—proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as, in form, suggested by or derived from the harp and psaltery, or from a "testa di porco" and an ordinary trapeze psaltery. We are inclined to prefer the latter. The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo (gravecembalo, or familiarly cembalo only) and clavecin. Much later, after the restoration of the Stuarts, the first name was accepted and naturalized in England as harpsichord, which we will define as the long quill instrument shaped like a modern grand piano, and resembling a wing, from which it has gained the German appellation "Flügel." We can point out no long

instrument of this kind so old as the Roman cembalo at South Kensington (fig. 11). It was made by Geronimo of Bologna in 1521, two years before the Paris Portalupis spinet. The outer case is of finely tooled leather. It has a spinet compass of keyboard of nearly four octaves, E to D. The natural keys are of boxwood, gracefully arcaded in front. The keyboards of the Italian cembalo were afterwards carried out to the normal four octaves. There is an existing example dated 1626, with the bass keys carried out without sharps in long measure. It is surprising to see with what steady persistence the Italians adhered in making the instrument to their original model. As late as the epoch of Cristofori, and in his 1722 cembalo at Florence, we still find the independent outer case, the single keyboard, the two unisons, without power to reduce to one by using stops. The Italians have been as conservative with their forms of spinet, and are to this day with their organs. The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este, by Count Valdrighi of Modena, after much consideration and a desire to find in it an anticipation of Cristofori's subsequent invention of the pianoforte, we are disposed to regard as an ordinary cembalo with power to shift, by a stop, from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition. About the year 1600, when accompaniment was invented for monody, large cembali were made for the orchestras to bring out the bass part—the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves—one hundred and twenty-five in all—to restore

FIG. 11.—Roman Clavicembalo, by Geronimo of Bologna, 1521; South Kensington Museum.

the three genera of the ancient Greeks. How many attempts have been made before and since Trasuntino to purify intonation in keyboard instruments by multiplying keys in the octave? Simultaneously with Father Smith's well-known experiment in the Temple organ, London, there were divided keys in an Italian harpsichord to gain a separate G sharp and A flat, and a separate D sharp and E flat.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations, quoted by Rimbault in his *History of the Pianoforte*, but imperfectly understood by him, are from the privy purse expenses of King Henry VIII., as extracted by Sir Harris Nicolas in 1827.

"1530 (April). Item the vj daye paid to William Lewes for ii payer of virginalls in one coffer with iii stoppes brought to Grenewiche iii li. And for ii payer of virginalls in one coffer brought to the More other iii li."

Now the second instrument may be explained, virginalls meaning any quilled instrument, as a double spinet, like that at Nuremberg by Martin Van der Beest, the octave division being movable; but the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double-keyed one, one keyboard being over, and not by the side of the other. Again from the inventory after the king's death—

"Two fair pair of new long Virginalls made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beastes within a garter gilt, standing over the keys."

Rimbault saw in this an upright instrument, and such a one was not then impossible, Virdung's clavichorium (fig. 12)

being no more than a horizontal harpsichord turned up upon its broad end, which a slight modification of the action rendered facile, but if upright, the two fair pair of new long virginalls would not have been "long"—but high. We explain "harp-fashion" according to Galilei's "arpa giacente," and are disposed to believe that we have here another double keyboard harpsichord. We read in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double virginalls," and in the Hengrave inventory, 1603, "one great payre of double virginalls." Hans Ruckers, the great clavisingel maker of Antwerp, lived then too late to have invented the double keyboard and stops, evident adaptations from the organ, but we may not withhold from him the credit of introducing the octave string, so long attributed to him, which incorporated the octave spinet with the large instrument, to be henceforth playable without the co-operation of another performer. It had been attached to the bent or angle side of harpsichords, as shown in a modern instrument which forms part of the famous Plantin Museum at Antwerp, and also in one by Hans Ruckers himself, dated 1594, preserved in the Kunst und Gewerbe Museum, Berlin. The double harpsichord by that maker at the Conservatoire, Paris, dated 1590, which is four years earlier than the above, has the octave string. From that date until the last harpsichord was made by Joseph Kirkman in 1798, scarcely an instrument of the kind was made, except in Italy, without the octaves. Hans Ruckers had two sons, Hans the younger and Andries the elder, who followed and rivalled him in skill and reputation. Another Andries, the son of the former, appears to have done but little, at least for himself; but a nephew, Jan Couchet, a grandson of old Hans Ruckers, continued the prestige of this distinguished family, Huygens being a witness to the rare ability of Couchet. All these men, and, in fact, all the clavisingel makers of Antwerp, belonged to the artist's guild of St Luke, the affiliation being recognized from the close alliance at that time of the arts, the painter having often as much to do with the musical instrument as the maker himself. The Ruckers harpsichords in the 18th century were fetching such prices as Bologna lutes did in the 17th or Cremona

FIG. 12.—Virdung's Clavichorium (upright Harpsichord), 1511.

violins do now. There are still many specimens existing in Belgium, France, and England. Handel had a Ruckers harpsichord, which may be the one long sought for and lately discovered by Mr Julian Marshall in Windsor Castle; it completes the number of sixty-three existing Ruckers instruments catalogued in Grove's *Dictionary of Music and Musicians*.

After the Antwerp make declined, London became pre-eminent for harpsichords,—the representative makers being Jacob Kirckmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Haendel became Handel, and Schmidt Smith, Kirckmann dropped his final *n* and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved in the New Palace, Potsdam. By these great makers the harpsichord became a larger, heavier-strung, and more powerful instrument, and fancy stops were added to vary the tone effects. To the three shifting registers of jacks of the octave and first and second unisons were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a surding or muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute, rendered practicable by first moving the "machine," a sixth stop, with the left hand of the player; the right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius, to whom also the harp stop may be rightly attributed. This ingenious harpsichord maker had been stimulated to gain these effects by the nascent pianoforte which, as we shall find, he was the first to make in England. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (? Haward) as early as 1676, as we learn from Mace's *Musick's Monument*. The French makers preferred a kind of knee-pedal arrangement known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and, becoming in England a favourite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecin brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

It was formerly a custom with kings, princes, and nobles who were well-disposed towards music to keep large collections of musical instruments,—not as now for beauty of decoration, form, and colour, or historical associations, but for actual playing purposes in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*,

a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Piano-forte*. We learn from it that in 1709 Cristofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German *hackbrett*, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it, the principle of escapement or the controlled rebound of the hammer, is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori in Florence, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument has undergone some restoration, but the 1726 one, which is in the Kraus Museum, retains the original leather hammerheads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have the "check" (Ital. *paramartello*) which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings. After this discovery of the actual instruments of Cristofori, there can be no longer doubt as to the attribution of the invention to him, in its initiation and its practical completion with escapement and check. To Cristofori we are indebted not only for the power of playing *piano* and *forte*, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

But his problem was not solved by the devising of a working action; there was much more to be done to instal the pianoforte as a new musical instrument. The reson-

FIG. 13.—Cristofori's Escapement Action, 1720.

ance, that most subtle and yet all-embracing factor, had been experimentally developed to a certain perfection by many generations of spinet and harpsichord makers, but the resistance structure had to be thought out again. Thicker stringing, rendered indispensable to withstand even Cristofori's light hammers, demanded, in its turn, a stronger framing than the harpsichord had needed. To make his structure firm, he considerably increased the strength of the block which holds the tuning-pins, and, as he could not do so without materially adding to its thick-

ness, he adopted the bold expedient of inverting it, driving his wrest-pins, harp-fashion, through it, so that tuning was effected at their upper, while the wires were attached to their lower ends.

Then to guarantee the security of the case he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian

pianoforte making, perhaps from the peculiar Italian conservatism in musical instruments we have already remarked upon.

The essay of Scipione Maffei was translated into German in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker.¹ Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz., that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it. It may be so; but Schroeter's letter, printed in Mitzler's *Bibliothek*, dated 1738, is not supported by any other evidence than the recent discovery of an altered German harpsichord, the hammer action of which, in its simplicity, may have been taken from Schroeter's diagram, and would sufficiently account for the condemnation of Silbermann's earliest pianofortes if he had made use of it. In either case it is easy to distinguish between the lines of Schroeter's interesting communications (to Mitzler and later to Marburg) the bitter disappointment he felt in being left out of the practical development of so important an instrument.

But, whatever Silbermann's first experiments were based upon, it has been made certain by the personal investigations of the present writer that he, when successful, adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys, and the style of joinery of the case. In the Silbermann grand pianofortes, in the three palaces at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank, and action complete. Fig. 15 represents the instrument on which J. S. Bach played in the Town Palace, Potsdam.

It has been repeatedly stated in Germany that Frederick of Gera in Saxony, an organ builder and musical instrument

FIG. 14.—Cristofori's Piano e Forte, 1726; Kraus Museum Florence.

¹ This translation, reproduced *in extenso*, may be read in Dr Oscar Paul's *Geschichte des Claviers*, Leipzig, 1868.

maker, invented the square or table-shaped piano, the "fort bien" as he is said to have called it, about 1758-60. No square piano by this maker is forthcoming, but M. Victor

do with the invention of it¹) a square piano, which was to become the most popular domestic instrument. Burney tells us all about Zumpe; and his instruments, still existing, fix the date of the first at about 1765. In his simple "old man's head" action, we have the nearest approach to a realization of Schroeter's simple idea. It will be observed that Schroeter's damper would stop all vibration at once. This defect is overcome by Zumpe's "mopstick" damper.

Another piano action had, however, come into use about that time or even earlier in Germany. The discovery of it in the simplest form is to be attributed to M. Mahillon, who has found it in a square piano belonging to M. Henri Gosselin, painter, of Brussels. The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and

FIG. 15.—Silbermann Forte Piano; Stadtschloss, Potsdam, 1746. Engraved by permission of H.I.H. the Crown Princess of Prussia.

Mahillon of Brussels has acquired a Frederici "upright grand" piano, dated 1745, and contributes a diagram of the simple action (fig. 16). In Frederici's upright grand action we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg, a fact which needs further elucidation. We note here the earliest example of the leather hinge afterwards so common in piano actions, and only now going out of use. Where are we to look for Schroeter's copyist, if not found in Silbermann, Frederici, or, as we shall presently see, perhaps Wagner? It might be in the harpsichord we have mentioned, which, made in 1712 by one Brock for the elector of Hanover (afterwards George I. of England), was by him presented to the Protestant pastor of Schulenberg near Hanover, and has since been rudely altered into a pianoforte (fig. 17). There is an altered harpsichord in the museum at Basel which appears to have been no more successful. But an attempted combination of harpsichord and pianoforte appears as a very early intention. The English poet Mason, the friend of Gray, bought such an

FIG. 16.—Frederici's Upright Grand Piano Action, 1746. Instrument now transferred to the museum of the Brussels Conservatoire.

FIG. 17.—Hammer and Lifter of altered Harpsichord by Brock. Instrument in the collection of Mr Kendrick Pyne, Manchester.

instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marburg's *Kritische Briefe* (Berlin, 1764). Now, immediately after, Johann Zumpe, a German in London who had been one of Shudi's workmen, invented or introduced (for there is some tradition that Mason had to

FIG. 18.—Schroeter's Model for an Action, 1721.

permit of its transformation into a square piano; a transformation, Schroeter tells us, had been going on when he

FIG. 19.—Zumpe's Square Piano Action, 1766.

wrote his complaint. It will be observed that the hammer is, as compared with other actions, reversed, and the axis

FIG. 20.—Old Piano Action on the German principle of Escapement. Square Piano belonging to M. Gosselin, Brussels.

risers with the key, necessitating a fixed means for raising the hammer, in this action effected by a rail against which the hammer is jerked up. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's

¹ Mason really invented the "celestina," as we know from the correspondence of Mary Granville. Under date of the 11th January 1775 she describes this invention or improvement of the poet as a short harpsichord in form, 2 feet long, but played with the right hand only. The left hand controlled a kind of violin-bow, which produced a charming *sostinente*, in character of tone between the violin tone and that of musical glasses. Mason played upon it with great expression.

approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind.

FIG. 21.—Stein's Action (the earliest so-called Viennese), 1780.

He had found the instrument that for the rest of his short life replaced the harpsichord. M. Mahillon has secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action, two unisons, and the knee pedal, then and later common in Germany.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved at Berlin and Charlottenburg, because they had belonged to the Prussian Queen Louise, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as *celeste*, which no doubt Stein had also. The wrest-plank is not inverted; nor is there any imitation of Cristofori. We may regard Stein, coming after the Seven Years' War which had devastated Saxony, as the German reinventor of the grand piano. Stein's instrument was accepted as a model, as we have seen, in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. She had her brother in the business with her, and had already, in 1793, married J. A. Streicher, a pianist from Stuttgart, and distinguished as a personal friend of Schiller. In 1802, the brother and sister dissolving partnership, Streicher began himself to take his full share of the work, and on Stein's lines improved the Viennese instrument, so popular for many years and famous for its lightness of touch, which contributed to the special character of the Viennese school of pianoforte playing. The firm of Streicher still exists in Vienna; but since 1862, when Steinway's example caused a complete revolution in German and Austrian piano-making, the old wooden cheap grand piano has died out. We will quit the early German piano with an illustration (fig. 22) of an early square piano action in an instrument

FIG. 22.—German Square Action, 1783. Piano by Wagner, Dresden.

made by Johann Gottlob Wagner of Dresden in 1783. This interesting discovery of M. Mahillon's introduces us to a rude imitation (in the principle) of Cristofori, and it appears to have no relation whatever to the clock hammer notion seen in Frederici's.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority we can refer to as to the introduction of the latter instrument into England. He tells us,¹ in his gossiping way, that the first hammer harpsichord that came to England was made by an English monk at Rome, a

¹ Rees's *New Cyclopædia*, article "Harpsichord."

Father Wood, for an English gentleman, Samuel Crisp of Chesington; the tone of this instrument was superior to that produced by quills, with the added power of the shades of *piano* and *forte*, so that, although the touch and mechanism were so imperfect that nothing quick could be executed upon it, yet in a slow movement like the Dead March in Saul it excited wonder and delight. Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyrichord, made a pianoforte in imitation of it. In this instrument the touch was better, but the tone was inferior. We have no date for Father Wood. Plenius produced his lyrichord, a *sostinente* harpsichord, in 1745. When Mason imported a pianoforte in 1755, Fulke Greville's could have been no longer unique. The Italian origin of Father Wood's piano points to a copy of Cristofori, but the description of its capabilities in no way supports this supposition, unless we adopt the very possible theory that the instrument had arrived out of order and there was no one in London who could put it right, or would perhaps divine that it was wrong. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers, said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, and, as this action is based upon Cristofori's, we may suppose he at first followed Silbermann in copying the original inventor. There is an old play-bill of Covent Garden in Messrs Broadwood's possession, dated the 16th May 1767, which has the following announcement:—

"End of Act 1. Miss BRICKLER will sing a favourite song from JUDITH, accompanied by Mr DIBDIN, on a new instrument call'd PIANO FORTE."

The mind at once reverts to Backers as the probable maker of this novelty. Be that as it may, between 1772 and 1776, the year of his death, he produced the action continued in the direct principle to this day by the firm of Broadwood, or with a reversed lever and hammer-butt introduced by the firm of Collard in 1835.

FIG. 23.—Grand Piano Action, 1776. The "English" action of Americus Backers.

The escapement lever is suggested by Cristofori's first action, to which Backers has added a contrivance for regulating it by means of a button and screw. The check is from Cristofori's second action. No more durable action has been constructed, and it has always been found equal, whether made in England or abroad, to the demands of the most advanced virtuosi. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the

he was certainly engaged upon the elementary action described as appertaining to M. Gosselin's piano, of probably German origin. In his long-continued labour of inventing and constructing a double escapement action, Erard appears to have sought to combine the English power of gradation of tone with the German lightness of touch. He took out his first patent for a "repetition" action in 1808, claiming for it "the power of giving repeated strokes without missing or failure, by very small angular motions of the key itself." He did not, however, succeed in producing his famous repetition, or double escapement action until 1821; it was then patented by his nephew Pierre Erard, who, when the patent expired in England in 1835, proved a loss from the difficulties of carrying out the invention, which induced the House of Lords to grant an extension of the patent.

Although some great pianists have been opposed to double escapement, notably Kalkbrenner, Chopin, and Dr Hans von Bülow, Erard's action, in its complete or a shortened form as introduced by Herz, is now more extensively used than at any former period. Erard invented in

Fig. 27.—Steinway's Grand Piano Action, 1884. The double escapement as in Erard's, but with shortened balance and usual check.

1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal through holes in which the strings are made to pass, bearing against the upper side. The wooden bridge with down-bearing strings is clearly not in relation with upward-striking hammers, the tendency of which must be to raise the strings from the bridge, to the detriment of the tone. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, M. Bord, and is very frequently employed, by German makers especially. The first to see the importance of iron sharing with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, who has been best known as the inventor of the ever-pointed pencil. He was living at Philadelphia U.S., when he invented and first produced the familiar cottage pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800. It will be observed that the illustration here given (fig. 26) represents a wreck; but a draughtsman's restoration might be open to question.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish pianomaker, had, in 1798, tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano, or pianino, with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame, independent

of the case ; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for

FIG. 28.—Hawkins's Portable Grand Piano, 1800. An upright instrument, the original of the modern cottage piano or pianino. In Messrs Broadwood's museum and unrestored.

tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. This remarkable bundle of inventions was brought to London and exhibited by Hawkins himself, but the instrument being poor in the tone failed to bring him pecuniary reward or the credit he deserved. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the high cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings, which is still frequently used with such actions. The next steps for producing the lower or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally and in 1813 a vertically strung one. Wornum's perfected crank action was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo." The principle of this centred lever check 'action' was introduced into Paris by Pleyel¹ and Pape, and thence has gone to Germany and America. In England it has now nearly superseded the once favourite leather-hinged action.

The diagram illustrates the internal mechanism of a piano action, focusing on the damper system. It shows a hammer flange at the top, which is designed to strike a damper flange located below it. A hammer butt is visible, connected to the hammer flange. The damper flange is part of a larger assembly that can move up and down to engage or disengage the damper from the hammer flange. The entire mechanism is housed within a wooden frame, with various levers and pivots shown in detail. The drawing is a technical illustration, likely from a historical treatise on piano construction.

FIG. 29.—Wornum's Upright Action, 1826. The original of the now universal crank action in upright pianos.

It was not, however, from Hawkins's invention that iron became introduced as essential to the structure of a pianoforte. This was due to William Allen, a young Scotsman in the employ of the Stodarts. He devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by

¹ Pleyel exhibited a small upright piano in Paris in 1827. Pierre Erard did not turn his attention to upright pianos until 1831.

atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross batoning of stout wooden bars and a metal bar across the wrest-plank. Allen, being simply a tuner, had not the full practical knowledge for carrying out the idea. He had to ally himself with Stodarts' foreman, Thom; and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent. We have now arrived at an important epoch in pianoforte construction,—the abolition, at least in England and France, of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig. 30. The long bars shown in the diagram are really tubes fixed at one end only; those of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings than could be stretched before, without danger to the durability of the case and frame. The next step was in 1821 to a fixed iron string-plate, the invention of one of Broadwoods' workmen, Samuel Hervé, which was in the first instance applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even solid counterpoise to the

FIG. 30.—Allen's Compensating Grand Piano, 1820. The first complete metal framing system applied over the strings.

drawing or tension of the strings and the abolition of their undue length behind the bridge, a reduction which Isaac Carter¹ had tried some years before, but unsuccessfully, to accomplish with a plate of wood. So generally was attention now given to improved methods of resistance that it has not been found possible to determine who first practically introduced those long iron or steel resistance bars which are so familiar a feature in modern grand pianos. They were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale as long ago as 1808, and again in 1818; he did not succeed, however, in fixing them properly. The introduction of fixed resistance bars is really due to observation of Allen's compensating tubes, which were, at the same time, resisting. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance bars from treble to bass, with a simple mode of fastening them through the sound-board to the wooden beams beneath, but, although these bars appear in their patent of 1824, which chiefly concerned their repetition action, the Erards did not either in France or England claim them as of original invention, nor is there any string-plate combined

with them in their patent. James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the nature of the resistance being fixed. Broadwood, however, left the bass bars out, but added a fourth bar in the middle to the three in the treble he had previously used. It must be borne in mind that it was the trebles that gave way in the old wooden construction before the tenor and bass of the instrument. But the weight of the stringing was always increasing, and a heavy close overspinning of the bass strings had become general. The resistance bars were increased to five, six, seven, eight, and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

The next important addition to the grand piano in order of time was the harmonic bar of Pierre Erard, introduced in 1838. This was a gun-metal bar of alternate pressing and drawing power by means of screws which were tapped into the wrest-plank immediately above the treble bearings; making that part of the instrument nearly immovable, this favoured the production of higher harmonics to the treble notes, recognized in what we commonly call "ring." A similar bar, subsequently extended by Broadwood across the entire wrest-plank, was to prevent any tendency in the wrest-plank to rise, from the combined upward drawing of the strings. A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, who had been in America with Chickering, and was a man of considerable inventive power. This invention was introduced in 1827. Between 1847 and 1849 Mr Henry Fowler Broadwood, son of James, and grandson of John Broadwood, and also great grandson of Shudi (Tschudi), invented a grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found.

FIG. 31.—Broadwood's Iron Grand Piano, 1884. Complete iron frame with diagonal resistance bar.

Mr Broadwood has not continued, without some compromise, this extreme renunciation of ordinary resistance means. Since the Great Exhibition of 1851 he has employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. From 1862 he has covered his wrest-plank with a thick plate of iron into

¹ Sometime foreman to the pianoforte maker Mott, who attracted much attention by a piano with sostenente effect, produced by a roller and silk attachments in 1817. But a sostenente piano, however perfect, is no longer a true piano such as Beethoven and Chopin wrote for.

which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string, an ultimate source of danger to durability.

The introduction of iron into pianoforte structure has been differently and independently effected in America, the fundamental idea there being a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphæus Babcock was the pioneer to this kind of metal construction. He also was bitten with the compensation notion, and had cast an iron ring for a square piano in 1825, which is not said to have succeeded, but gave the clew to a single casting resistance framing, which was successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was taken up and improved upon by Jonas Chickering of Boston, who applied it to the grand piano as well as to the square, and brought the principle up to a high degree of perfection,—establishing by it the independent construction of the American pianoforte.

We have now to do with over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale in a single, double, or treble disposition at diverging angles,—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavicords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Geroch & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanic in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Lichtenthal of St Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. A few years later, in 1855, Henry Engelhard Steinway (originally Steinweg), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which, exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading ultimately to important results. The Chickering firm claim to have anticipated the Steinways in this invention. They assert that Jonas Chickering had begun a square piano on this combined system in 1853, but, he dying before it was completed, it was brought out later. It is often difficult to adjudicate

FIG. 32.—Meyer's Metal Frame for a Square Piano, 1833. In a single casting.

upon the claims of inventors, so rarely is an invention the product of one man's mind alone. However, the principle has been taken up and generally adopted in America and Germany, and has found followers elsewhere, not only in grand but in upright pianos, to the manufacture of which it has given, and particularly in Germany, a powerful impetus. But, in spite of this general recognition, the overstringing, as at present effected, is attended with grave disadvantages, in disturbing the balance of tone by introducing thick, heavy basses, which, like the modern pedal organs, bear no just relation to that part of the keyboard where the part-writing lies. The great increase

also of tension which is held up as a gain, acts prejudicially upon the durability of the instrument, as no artificial screwing up of the sound-board can always preserve the elasticity of the fibres of the fir tree (*Abies excelsa* in Europe, *Abies alba* in America) of which it is made. The remarkable improvements in the drawing of the cast steel wire produced in Birmingham, Vienna, and Nuremberg (this last initiated by Boehm) have rendered very high

tensions practicable. We believe they have been overstated in figures; it is certain, however, that Broadwood's seven-octave concert grands have a tension of not less than sixteen tons when at the English orchestral pitch,—the notes of the ideal lengths each drawing 450 lb. We have no such accurate statement to offer of the American and German concert grands, but we regard Steinway's as of not less than twenty-two tons tension.

Whatever of importance has been introduced in the structure of the pianoforte we believe we have attributed to its legitimate inventor or to the manufacturer who has placed it in the light of day. It would be impossible within reasonable limits to chronicle the variations which have taken place in the barrings of sound-boards on which their resonant structure depends, the disposition of wooden beams or metal bars, the adaptation of mechanical action, or any of those countless modifications upon which finally depends the individual character of an instrument worthy to be presented and upheld as a work of art. There are many names of first-rate pianoforte makers whose place has not been in this record, simply because they have not ranked with the initiators or perfectors of inventions that have been accepted as of paramount importance.

The earliest keyboard instrument makers were to be found in monasteries or collegiate foundations, and such lay help as may have been employed was at best of the roughest kind. In the next epoch the artists' guilds in cities absorbed lay musical instrument makers, notably on account of the then universal practice of making such instruments beautiful; and, indeed, we are indebted to this for the preservation of many spinets and harpsichords in museums and private collections. The full members of the craft-

FIG. 33.—Steinway's Grand Piano, 1884. Metal framing in a single casting and overstrung.

guilds were all masters who had terminated their apprenticeships by producing complete instruments as "master-pieces," made according to the rules and to the satisfaction of the wardens or deacons of the guilds. A trial of this kind lasted long in many crafts—for instance, in the case of Scottish cabinetmakers' indentures, an apprentice's freedom was only gained after the test production of an "essay" piece of work, duly authenticated and admitted. Spinets and harpsichords were bound to bear the inscription of the maker's name, or to show his trade mark as a guarantee for honest workmanship. The master's sons and apprentices were, in the master's workshops, probationers of the guild and protected by it. Even in the 17th century we hear little about journeymen, who, as the name implies, would be paid by the day. But the extension of musical instrument workshops about the beginning of the 18th century was one of the signs of the weakened power of the guilds—particularly in Great Britain. In France it needed the Revolution to entirely abolish them.

Throughout the 18th century journeywork and apprenticeship were general. Wages, compared with the cost of living, were meagre, and the day's work, not unfrequently extended by overtime, was a long one. The result was a slow production. The English cabinet-makers, however, owing to disputes which at last called for judicial interference, in the year 1788 brought out their book of prices which was the foundation of the present piece-work system. Pianoforte makers in course of time adopted this new departure with the result of quicker work and higher wages, benefiting alike the master and man. The next industrial revolution was inaugurated somewhere about 1815, by the introduction of machinery to save manual labour, the division of which had already been instituted, and by the use of steam. Machinery has, as yet, been extended to its furthest limit in America, where labour-saving is relied upon as a powerful ally against strikes, which are more frequently victorious in the New than in the Old World. Simultaneously a dislike has arisen to apprenticeships; and even in Germany, the traditional land of the apprentice, this mode of acquirement has weakened.

Turning to the commercial importance of the pianoforte, we find that we have to face great difficulties in order to obtain anything like trustworthy information. It is true official blue-books give yearly statements of exports and imports, but as they do not separate the pianoforte from other musical instruments an analysis is impossible. Personal inquiry again among pianoforte makers brings but scattered information, partly from the natural inclination to enhance business returns, and partly from an equally natural disinclination to impart that which, if spoken of at all, should be confidential. From this dilemma we fall back upon gleanings of intelligence either of our own gathering or as afforded by the leading pianoforte trade organs in England and Germany—the *London Music Trades Review* and the *Leipziger Zeitschrift für Instrumentenbau*.

The chief centres of the pianoforte trade are London, Paris, Berlin, Leipzig, Dresden, Stuttgart, Hamburg, Vienna, St Petersburg, Brussels, New York, Boston, and Baltimore. The greatest centralizations are found in London and Paris,—very few pianofortes being made in the United Kingdom or France, excepting perhaps at Marseilles, out of those cities. But in Germany and the United States there are pianoforte makers in many towns besides those we have named. Pianofortes are made in Italy at Turin, Milan, Florence, Naples, and Palermo, and in Spain at Barcelona (principally), Madrid, and Saragossa. The large export trade belonged formerly to England and France, but it has been weakened of late years by the commercial activity of the Germans, who have besides copied successfully and with the advantage of much lower wages recent American models. German pianofortes are now much found in Great Britain, where free trade has favoured their introduction, and in the Australian colonies; they have also outrivalled the French in Holland; but we believe France still keeps the trade of southern Europe, as the United States mainly supply Canada. English exports of good makers will be found all over the world; but some important markets have been lost through the inferior instruments consigned or sold because they were cheap, and were supposed to be good enough.

The United States and Germany appear to employ the greatest number of workmen in the pianoforte handicraft, Germany producing the largest numbers of instruments. In adopting, however, the statistics given, we must not forget to take into account that custom of advertising which leavens nearly every statement. There are said to be upwards of 8000 workmen employed in pianomaking in America. The Messrs Steinway claim for America an annual production of 25,000 pianofortes of all kinds, and it may be more. We hardly feel disposed to allow Germany 73,000, with a less number of workmen, viz., 7834; but such is the statement put forward by a semi-official source, the *Deutsche Consulats-Zeitung*. It must be borne in mind that machinery adds its power indefinitely to the number of men employed, but this occurs more in America than in Germany. A recent strike in Paris represented the pianoforte trade society as consisting of 5000 members; and we may safely credit that city with a production of 20,000 instruments yearly. The number made in London annually may be taken as reaching at least 35,000; it is probably larger.

PIARISTS, the popular name of the "clerici regulares scholarum piarum," the Pauline Congregation of the Mother of God, which was founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the 17th century. Calasanza, a native of Calasanz in the province of Huesca in Aragon, was born on September 11, 1556, studied at Lerida and Alcala, and after his ordination to the priesthood removed to Rome. Here he became zealously interested in the education of poor and orphan children, and with this end he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant orders conferred upon it, Calasanza being recognized as general. In this capacity he busied himself with the extension of the order, not only in Italy, but also in Germany, Poland, and other countries, until 1643, when the jealousy of the Jesuits led to conflicts which resulted in his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanza, who died on August 22, 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1669, and 1698. The Piarists, who are not a numerous body, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary.

PIATRA, a town of Roumania (Moldavia) at the head of the department of Neamtso, on the left bank of the Bistritza, an affluent of the Sireth. It is about 45 miles

by road from Roman, a station on the railway from Galatz and Czernowitz. The population of the prefecture in 1878 was 25,383 (9887 Jews). It contained seven Orthodox churches,—the most remarkable being St John's, or the Prince's Monastery, founded by Stephen the Great in 1497. There are five annual fairs, and a large trade is done in grain and timber—the latter being rafted down the Bistritza from the mountains to Galatz.

PIAZZA ARMERINA (Sicilian, *Chiazza*), a city of Italy, in the province of Caltanissetta, Sicily, on a hill 39 miles by road east-south-east of the city of that name, and 30 miles north of Terranova on the coast. It is a flourishing and populous place (17,038 inhabitants in the city and 19,591 in the commune in 1881), has an 18th-century cathedral, an episcopal palace, and a communal library (1859). The church of Sant' Andrea, less than a mile distant, has a fresco of date 1486, and other objects of interest.

Of the ancient city, which old local antiquaries held to have been built by a colony of refugees from Plataea, little is known. The name sometimes occurs as Plutia. In 1095 Piazza was taken by Count Roger of Sicily, who bestowed on it a banner reputed to bear a likeness of the Virgin painted by St Luke. William I. destroyed the city in 1160, but it was rebuilt on a new site in 1163.

See *Piazza antica*, &c., by J. P. Chiaranda (a native), of which a Latin translation by Mosheim is given in Grævius's *Thesaurus ant. et hist. Sic.*, vol. xii.

PIAZZI, GIUSEPPE (1746–1826). See ASTRONOMY.

PICARDY (*La Picardie*), one of the old feudal provinces of France, was bounded N. by Hainault, Artois, and the English Channel, E. by Champagne, S. by Île-de-France, and W. by Normandy and the Channel. Northern Picardy (subdivided into Upper and Lower Picardy) was formed into one of the great military governorships of the kingdom, while Southern Picardy was included in the governorship of Île-de-France. Upper Picardy comprised the districts (*pays*) of Amienois, Santerre, Vermandois, and Thierache; Lower Picardy Boulonnais, Ponthieu, Vimeu, and the Pays Reconquis (or Calais, Guines, Ardre, and Oye); and Southern Picardy Beauvaisis, Soissonais, and Laonnais. The territory is now divided among the departments of Pas-de-Calais, Somme, Aisne, Oise, and Nord.

The name Picardy does not appear before the 13th century. Under the Romans the country formed part of Belgica Secunda, and was inhabited by various Belgian tribes—the Morini, Ambiani, Veromandui, Bellovaci, and Suessiones, whose names still appear in Amiens, Vermandois, Beauvais, and Soissons. After forming part of the kingdom of Soissons and of Neustria, Picardy (that is, the countship of Vermandois, &c.) passed to the counts of Flanders. It was finally united with the French crown by Louis XI.

See De Verité (1770–74), Dubelloy (1770), La Bourd (1840), Roger (1842–43), and Cocheris (1854). V. de Beauville has published a magnificent *Recueil de documents inédits concernant la Picardie*, 1861, 1867, &c.

PICCINI, or PICCINNI, NICCOLA (1728–1800), musical composer, was born at Bari in 1728, and educated, under Leo and Durante, at the Conservatorio di San Onofrio in Naples. His first opera, *Le Donne dispettose*, produced in 1754, won him a high reputation, which he maintained creditably until 1760, when he composed, at Rome, the *chef d'œuvre* of his early life, *La Cecchina, ossia la Buona Figliuola*, an *opera buffa* which attained a European success, little less remarkable than that of Pergolesi's *Serva Padrona*. In a very short time this charming piece found its way not only to every theatre in Italy, but to Paris, to London, and to every great city on the Continent. It was even represented by marionettes; and every new fashion was named *alla Cecchina*. Six years after this Piccini was invited to Paris. He knew nothing of French, but his librettist, Marmontel, assisted him to such good purpose that, after the production of his first French opera, *Roland*, he was carried home from the theatre in triumph. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. The Parisian public now divided itself into two rival parties,

which, under the names of Gluckists and Piccinists, carried on an unworthy and disgraceful war, equally ruinous to both artists, who would gladly have withdrawn from its violent excesses. That the final victory should be obtained by the Gluckists was inevitable; for Piccini, though a brilliant ornament of the Italian school, was no match for his illustrious antagonist. Gluck's masterly *Iphigénie* was first produced on May 18, 1779. Piccini's *Iphigénie* followed on January 23, 1781, and, though performed seventeen times, was afterwards consigned to oblivion. The fury of the rival parties continued unabated, even after Gluck's departure from Paris in 1780; and an attempt was afterwards made to inaugurate a new rivalry with Sacchini. Still, Piccini held a good position, and on the death of Gluck, in 1787, proposed that a public monument should be erected to his memory,—a suggestion which the Gluckists themselves declined to support. On the breaking out of the Revolution in 1789, Piccini returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples, and Rome; but, deriving new hope from the declaration of peace, he returned in 1798 to Paris, where the fickle public received him with enthusiasm, but left him to starve. He died at Passy, May 7, 1800.

Fétis gives a complete list of Piccini's works, including eighty operas, and much choral music. It is certain that the list of operas is very far from complete.

PICENUM. See ITALY, vol. xiii. pp. 444, 447.

PICHEGRU, CHARLES (1761–1804), the conqueror of Holland, was born at Arbois in the Jura on February 16, 1761. His father was only a labourer, but the friars who managed the college of Arbois gave the boy a good education, and one of his masters, the Père Patraut, took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. When the Revolution began he at once became leader of the extreme revolutionary party in Besançon, where he was stationed; and, when a regiment of volunteers of the department of the Gard marched through the city, the popular society recommended him for the rank of lieutenant-colonel, to which he was at once elected. The fine condition of his regiment was soon remarked in the army of the Rhine, to which it was attached, and his organizing ability was made use of by an appointment on the staff, and finally by his promotion to the rank of general of brigade. In 1793, when Dumouriez had deserted, and all generals of noble birth had been superseded, Carnot and Saint Just were sent to find *roturier* generals who could be successful; Carnot discovered Jourdan, and Saint Just discovered Hoche and Pichegru. In co-operation with Hoche and the army of the Moselle, Pichegru, now general of division and in command of the army of the Rhine, had to reconquer Alsace and reorganize the disheartened troops of the republic. They succeeded; Pichegru, instead of fighting great battles, made use of the *élan* of his soldiers to win innumerable small engagements, and with Hoche forced the lines of Haguenau, and relieved Landau. In December 1793 he superseded Hoche, became commander-in-chief of the united armies of the Rhine and Moselle, whence he was summoned to succeed Jourdan in the army of the North in February 1794. It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated Clerfayt at Cassel, Menin, and Courtrai, while Moreau, his second in command, defeated Coburg at Turcoing in May 1794; then after a pause, during which

Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hoogdele, while Jourdan came up with the new army of the Sambre and Meuse, and utterly routed the Austrians at Fleurus on June 27, 1794. After a pause Pichegru began his second campaign by crossing the Meuse on October 18, and after taking Nimeguen drove the Austrians beyond the Rhine. Instead of going into winter-quarters, he prepared his army for a winter campaign. On December 28th he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on January 19, and Amsterdam on January 20, and soon occupied the whole of Holland. This grand feat of arms was marked by many points of interest, such as the capture of the Dutch ships which were frozen in the Helder by the French hussars, and the splendid discipline of the ragged battalions in Amsterdam, who, with the richest city of the Continent to sack, yet behaved with perfect self-restraint. This conquest aroused a storm of admiration in France. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of Sauveur de la Patrie, subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (1 April). Honoured by the republicans, and with the greatest military reputation in France, Pichegru then took command of the armies of the North, the Sambre and Meuse, and the Rhine, and crossing the Rhine in force took Mannheim in May 1795. When his fame was thus at its height he became a traitor, and for the promise of a marshal's baton, the governorship of Alsace, the castle of Chambord, 1,000,000 francs in cash, and 200,000 francs a year, sold his army and his country. He allowed Jourdan to be beaten before Mannheim, and betrayed all his plans to the enemy. His intrigues were suspected, and when he offered his resignation to the Directory in October 1795 it was to his surprise promptly accepted. He retired in disgrace, but hoped to serve the royalist cause by securing his election to the Council of Five Hundred in May 1797. He was there the royalist leader, and planned a *coup d'état*, but on the 18th Fructidor he was arrested, and with fourteen others deported to Cayenne in 1797. Escaping, he reached London in 1798, and served in the archduke Charles's staff in the campaign of 1799. He went to Paris in August 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but, betrayed by a friend, he was arrested on February 28, 1804, and on April 6th was found strangled in prison. It has often been asserted, but without a shadow of probability, as he was certain to have been condemned if brought to trial, that he was murdered by the orders of Napoleon.

Pichegru's campaigns of 1794 are marked by traits of an audacious genius which would not have disgraced Napoleon; like him, he perceived the intrinsic fitness of the French soldiers for strokes of daring rather than for sustained battles. But a more thorough traitor never commanded an army. He flattered in turn Saint Just and the Terrorists, the Thermidorians and the Directors, and seemed altogether unmoved by considerations of loyalty or patriotism.

There is no really good life of Pichegru; perhaps the best is Gassier's *Vie du général Pichegru*, Paris, 1814. For his treason, trial, and death consult Montgallard's *Mémoires concernant la trahison de Pichegru*, 1804; Fauche-Borel's *Mémoires*, Savary, *Mémoires sur la Mort de Pichegru*, Paris, 1825; and G. Pierret, *Pichegru, son Procès et son Mort*, 1828.

PICKLES. The term pickle was originally applied to herrings preserved in salt brine, and by a pickle is still meant any preservative solution for either animal or vegetable food, that for flesh and fish being a brine of common salt, usually with saltpetre, sugar, and certain spices added, while for vegetable substances vinegar is the principal pickling medium. Preparations of the latter description—vegetables saturated with vinegar—constitute the ordinary pickles of domestic use. Acid fruits and succulent fleshy vegetables are the proper materials for pickles.

The vegetable substances principally treated in this way are—beetroot, cabbage, cauliflower, gherkins (small cucumbers), capers, French beans, onions, shallots, mushrooms, green peaches, mangoes, green walnuts, and several tropical fruits besides those mentioned. These are variously dealt with. Such as are soft and in themselves hot and spicy require simply to have vinegar of the proper strength poured over them, after the materials have been carefully selected, washed, and, if necessary, shred. Vegetable substances of a harder and tougher character require first to be steeped in salt brine for some time, then washed, and the vinegar poured over them hot; and yet more leathery and fibrous vegetables must be softened with boiling brine, and then prepared with boiling vinegar. The vinegar employed may be either wood or strong malt vinegar; the former, being free from mucilage, has no tendency to fermentation, and can be obtained of greater strength than that prepared from malt. The vinegar is commonly flavoured with spices or aromatic herbs, flavours being chosen with special reference to the fruit or vegetable operated on. The flavouring materials, of which pepper, allspice, red pepper, cloves, horse-radish, garlic, and ginger are examples, are either added whole to the pickle or may be separately infused in the vinegar. For the preservation of pickles it is necessary that the jars in which they are stored should be secured with stoppers tied over with bladder and sealed, so as to render them as far as possible air-tight. It is of the utmost consequence that in the compounding and storing of these acid preparations no vessels or fittings of copper, brass, zinc, or lead, which yield, with acetic acid, poisonous products, should be used. Contamination with copper is especially to be avoided; yet, as small quantities of acetate of copper give to pickled vegetables a fine, fresh green, natural colour, such an adulteration is not unfrequently practised; and some of the older cookery books actually recommend the use of copper vessels, and even the addition of small pieces of verdigris, to improve the colour of the pickles. As food adjuncts, pickles should be sparingly used, their chief merit being piquancy, though the acid they contain exercises a solvent influence on the more directly nutritious constituents of food, and, the added spices having a stimulating effect, they thus aid the process of digestion.

PICO, GIOVANNI, OF MIRANDOLA (1463–1494), was the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory about 30 Italian miles west of Ferrara, afterwards absorbed in the duchy of Modena. The family was illustrious and wealthy, and claimed descent from Constantine. From his childhood Pico was remarkable for his quick and tenacious memory, and gave promise of his future distinction as a scholar. In his fourteenth year he went to Bologna, where he studied for two years, and was much occupied with the Decretals. The traditional studies of the place, however, disgusted him; he was eager to know all the secrets of nature, and devoting himself wholly to speculative learning he spent seven years wandering through all the schools of Italy and France and collecting a precious library. Like most men with brilliant faculties of acquisition and assimilation, Pico was constitutionally an eclectic; and he owes his place in the history of learning and thought to the indefatigable spirit of inquiry which left him dissatisfied with current teaching and drove him to studies then new and strange. Besides Greek and Latin he knew Hebrew, Chaldee, and Arabic; and his Hebrew teachers (Elijah del Medigo, Leo Abarbanel, and Jochanan Aleman—see L. Geiger, *Johann Reuchlin* [1871], p. 167) introduced him to the Kabbalah, which had great fascinations for one who loved all mystic and theosophic speculation. His learned wanderings ended at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of

philosophy and theology. He remained a year in Rome, but the disputation he proposed was never held. He was an object of envy to many for the range of attainments, which earned him the title of the Phoenix of his age, and detractors found it easy to fix on his conclusions a suspicion of heresy. The pope prohibited the little book in which they were contained, and Pico had to defend the impugned theses in an elaborate *Apologia*. His personal orthodoxy was, however, finally vindicated by a brief of Alexander VI., dated 18th June 1493. The suspected theses included such points as the following:—that Christ descended *ad inferos* not in his real presence but *quoad effectum*; that no image or cross should receive *latreia* even in the sense allowed by Thomas; that it is more reasonable to regard Origen as saved than as damned; that it is not in a man's free will to believe or disbelieve an article of faith as he pleases. But perhaps the most startling thesis was that no science gives surer conviction of the divinity of Christ than "magia" (*i.e.*, the knowledge of the secrets of the heavenly bodies) and Kabbalah. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries, and it was by him that Reuchlin was led into the same delusive path.

Pico had been up to this time a gay Italian nobleman; he was tall, handsome, fair-complexioned, with keen grey eyes and yellow hair, and a great favourite with women. But his troubles led him to more serious thoughts; he burned his amorous verses and gave himself wholly to sacred letters, publishing as the first fruits of his studies, in his twenty-eighth year, the *Heptaplus*, a mystical exposition of the creation. Next he planned a great sevenfold work against the enemies of the church, of which only the section directed against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marsilius Ficinus, and where also he came under the influence of Savonarola. It was at Florence that he died in 1494. Three years before his death he parted with his share of the ancestral principality, and gave much of his wealth to the poor. He was now increasingly absorbed in ascetic exercises and religious meditation, and designed, when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching Christ, or perhaps to join the preaching friars. But these plans were cut short by a fever which carried him off just at the time when Charles VIII. was at Florence. Pico's attainments and the beauty of his character and piety produced a profound impression on his contemporaries, but his works, published by his nephew Giov. Fran. Pico, with a biography, at Bologna in 1496, and more than once reprinted, cannot now be read with much interest. The man himself, however, is still interesting, partly from his influence on Reuchlin and partly from the spectacle of a truly devout mind in the brilliant circle of half-pagan scholars of the Florentine renaissance.

PICTON, SIR THOMAS (1758–1815), general under Wellington in the Peninsular War, was the younger son of Thomas Picton, of Poyston, Pembrokeshire, where he was born in August 1758. In 1771 he obtained an ensign's commission in the 12th regiment of foot, but he did not join until two years afterwards. The regiment was then stationed at Gibraltar, where he remained until he was made captain in the 75th in January 1778, when he returned to England. The regiment was shortly afterwards disbanded, and in 1794 he embarked for the West Indies without an appointment, on the strength of a slight acquaintance with Sir John Vaughan, who made him his aide-de-camp and gave him a captaincy in the 17th foot. Shortly afterwards he was promoted major. Under Sir Ralph Abercromby he took part in the capture of St Lucia

and St Vincent. After the reduction of Trinidad he was made governor of the island, and in October 1801 he was gazetted brigadier-general. Resigning the governorship of Trinidad in 1803, he took part in an expedition against St Lucia and Tobago, and he held the governorship of the latter island until forced to resign it by public clamour in England. In 1807 he was put upon his trial for applying torture to a female slave in Trinidad to extort confession respecting a robbery, and a general verdict of guilty was returned. A new trial was, however, granted, and after protracted litigation the court, on 10th February 1810, ordered "the defendant's recognizance to be respited until they should further order." Previous to this he had taken part in the capture of Flushing, of which in 1809 he was made governor. At the special solicitation of Wellington he was named to the command of a division of the army in Spain, and during the Peninsular campaign he was placed in the post of honour, and so distinguished himself that he seven times received the thanks of the House of Commons. The capture of Badajoz was effected chiefly through his daring self-reliance and penetration in converting what was intended to be only a feint attack into a real one. At the battle of Quatre Bras on the 16th June 1815 he was dangerously wounded, and at Waterloo on the 18th, while repulsing with impetuous valour what Wellington denominated "one of the most serious attacks made by the enemy on our position," he was struck dead by a ball on the temple. A public monument was erected to his memory in St Paul's Cathedral.

PICTS. See SCOTLAND.

PIEDMONT (Italian, *Piemonte*; Low Latin, *Pedemonis* and *Pedemontium*), a region of northern Italy, bounded N. by Switzerland, W. by France, S. by Liguria, and E. by Lombardy. Physically it may be briefly described as the upper gathering-ground and valley of the river Po, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime, and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara, and Torino (Turin), which still remain as provinces of the kingdom of Italy. In 1858 its population was 2,738,814.

The name of Lombardy was used as inclusive of the upper valley of the Po as late as 1091, when the house of Savoy lost most of its Italian possessions by the death of Adelaide; but in the time of Thomas I. (1177–1233), duke of Savoy, while the name Savoy was applied more especially to the ducal territory on the French side of the Alps, that of Piedmont came into use as a collective term for the territory on the Italian side. Thomas II. of Savoy, count (not Thomas I., count of Savoy, as he is often wrongly called), son of Thomas I., obtained (1255) part of Piedmont as an appanage from his brother Amadeus IV., and was appointed imperial vicar in Piedmont by Frederick II.; and, though he was afterwards obliged to renounce all the concessions he had received alike from pope and emperor, his son Thomas III. became the founder of the line which bore the title "Princes of Achaia and Morea, and lords of Piedmont." Louis, the last of these lords, dying in 1418, left his possessions to Amadeus VIII.

PIERCE, FRANKLIN (1804–1869), fourteenth president of the United States, was descended from an old yeoman family of New England, and was born at Hillsborough, New Hampshire, 23d November 1804. His father, Benjamin Pierce, served through the revolutionary war, afterwards attaining the rank of major-general, and became governor of his State. The son entered Bowdoin College, Brunswick, Maine, in 1820. Nathaniel Hawthorne, who was in the class below him, and was his intimate friend, mentions as his most notable characteristic at this time his "fascination of manner, which has proved so magical in winning him an unbounded popularity." The same characteristic remained with him through life, and was the chief

cause of his success. His abilities did not greatly impress his classmates, and, although he took at length a good position, he was not distinguished for scholarship. After leaving college in 1824 he studied law with Judge Woodbury at Portsmouth, and afterwards in the law school at Northampton, Mass., and with Judge Parker at Amherst, and came to the bar in 1827. His first appearance as a pleader was a failure, but this only incited him to redoubled perseverance and determination. From the first he was a zealous supporter of the Democratic party, and he took an active part in promoting the election of Andrew Jackson to the presidency. In 1829 he was elected by his native town to the State legislature, of which he was speaker in 1832-33. In the latter year he was chosen a member of Congress, and in 1837 he was elected to the senate of the United States. He displayed no striking oratorical gifts, but as a member of the judiciary and other committees gained general respect. In 1842 he resigned his seat in the senate, and returned to the practice of the law. His reputation at the bar was very high, his success being largely due to his power of identifying himself with his client's cause, and his strong personal influence over a jury. In 1846 he was offered the position of attorney-general of the United States, but declined it. On the outbreak of the Mexican War he joined as a volunteer one of the companies raised in Concord. He was soon after appointed colonel of the 9th regiment, and in March 1847 brigadier-general. At the battle of Contreras on the 19th of August he was severely injured by the fall of his horse. At the close of the war in December 1847 he resigned his commission. In 1850 he was president of the convention for revising the constitution of New Hampshire. In 1852, as candidate of the Democratic party, he was elected president of the United States by 254 electoral votes against 42 given to General Scott. The special feature of his inaugural address was the support of slavery in the United States, and the announcement of his determination that the Fugitive Slave Act should be strictly enforced. This was the keynote of his administration, and pregnant with vital consequences to the country. From it came during his term the Ostend conference and "manifesto," the repeal of the Missouri compromise, and the troubles in Kansas and Nebraska, which crystallized the opposing forces into the Republican party, and led later to the great rebellion. President Pierce, surrounded by an able cabinet, among them Jefferson Davis as Secretary of War, firmly adhered throughout his administration to the pro-slavery party. He failed, notwithstanding, to obtain re-nomination, but was succeeded by James Buchanan, March 4, 1857, and retired to his home in Concord, N. H., after spending some years in Europe. During the war of 1861-65 his sympathies were wholly with the South, but, with the exception of delivering a strong speech at Concord in 1863, he took no very active part in politics. He died 8th October 1869.

Among several lives of General Pierce, published during his candidature for the presidency, special mention may be made of that by his friend Nathaniel Hawthorne.

PIERO (or PIETRO) DE' FRANCESCHI (1415-1492), a leading painter of the Umbrian school. This master is generally named Piero della Francesca (Peter, son of Frances), the tradition being that his father, a woollen-draper named Benedetto, had died before his birth. This is not correct, for the mother's name was Romana, and the father continued living during many years of Piero's career. The painter is also named Piero Borghese, from his birthplace, Borgo San Sepolcro, in Umbria. The true family name was, as above stated, Franceschi, and the family still exists under the name of Martini-Franceschi.

Piero first received a scientific education, and became an adept in mathematics and geometry. This early bent

of mind and course of study influenced to a large extent his development as a painter. He had more science than either Paolo Uccello or Mantegna, both of them his contemporaries, the former older and the latter younger. Skilful in linear perspective, he fixed rectangular planes in perfect order and measured them, and thus got his figures in true proportional height. He preceded and excelled Domenico Ghirlandajo in projecting shadows, and rendered with considerable truth atmosphere, the harmony of colours, and the relief of objects. He was naturally therefore excellent in architectural painting, and, in point of technique, he advanced the practice of oil-colouring in Italy.

The earliest trace that we find of Piero as a painter is in 1439, when he was an apprentice of Domenico Veneziano, and assisted him in painting the chapel of S. Egidio, in S. Maria Novella of Florence. Towards 1450 he is said to have been with the same artist in Loreto; nothing of his, however, can now be identified in that locality. In 1451 he was by himself, painting in Rimini, where a fresco still remains. Prior to this he had executed some extensive frescos in the Vatican; but these were destroyed when Raphael undertook on the same walls the Liberation of St Peter and other paintings. His most extensive extant series of frescos is in the choir of S. Francesco in Arezzo,—the History of the Cross, beginning with legendary subjects of the death and burial of Adam, and going on to the entry of Heraclius into Jerusalem after the overthrow of Chosroes. This series is, in relation to its period, remarkable for effect, movement, and mastery of the nude. The subject of the Vision of Constantine is particularly vigorous in chiaroscuro; and a preparatory design of the same composition was so highly effective that it used to be ascribed to Giorgione, and might even (according to one authority) have passed for the handiwork of Correggio or of Rembrandt. A noted fresco in Borgo San Sepolcro, the Resurrection, may be later than this series; it is preserved in the Palazzo de' Conservatori. An important painting of the Flagellation of Christ, in the cathedral of Urbino, is later still, probably towards 1470. Piero appears to have been much in his native town of Borgo San Sepolcro from about 1445, and more especially after 1454, when he finished the series in Arezzo. He grew rich there, and there he died, and in October 1492 was buried.

Two statements made by Vasari regarding "Piero della Francesca" are open to much controversy. He says that Piero became blind at the age of sixty, which cannot be true, as he continued painting some years later; but scepticism need perhaps hardly go to the extent of inferring that he was never blind at all. Vasari also says that Fra Luca Pacioli, a disciple of Piero in scientific matters, defrauded his memory by appropriating his researches without acknowledgment. This is hard upon the friar, who constantly shows a great reverence for his master in the sciences. One of Pacioli's books was published in 1509, and speaks of Piero as still living. Hence it has been propounded that Piero lived to the patriarchal age of ninety-four or upwards; but, as it is now stated that he was buried in 1492, we must infer that there is some mistake in relation to Pacioli's remark—perhaps the date of writing was several years earlier than that of publication. Piero was known to have left a manuscript of his own on perspective; this remained undiscovered till a recent date, when it was found by E. Harzen in the Ambrosian Library of Milan, ascribed to some supposititious "Pietro, Pittore di Bruges." The treatise shows a knowledge of perspective as dependent on the point of distance.

In the London National Gallery are four paintings attributed to Piero de' Franceschi. One of them, a profile of Isotta da Rimini, may safely be rejected. The Baptism of Christ, which used to be the altarpiece of the Priory of the Baptist in Borgo San Sepolcro, is an important example; and still more so the Nativity, with the Virgin kneeling, and five angels singing to musical instruments. This is a very interesting and characteristic specimen, and has indeed been praised somewhat beyond its deservings on æsthetic grounds.

Piero's earlier style was energetic but unrefined, and to the last he lacked selectness of form and feature. The types of his visages are peculiar, and the costumes (as especially in the Arezzo series)

singular. He used to work assiduously from clay models swathed in real drapery. Luca Signorelli was his pupil, and probably to some extent Perugino; and his own influence, furthered by that of Signorelli, was potent over all Italy. Belonging as he does to the Umbrian school, he united with that style something of the Siennese and more of the Florentine mode.

PIETISM. Pietism is the name of an exceedingly influential, instructive, and interesting movement in the Lutheran Church which arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement by its enemies, as a term of ridicule, like that of "Methodists" somewhat later in England. The origin and nature of the movement itself may be both traced to defects in the Lutheran Church of the time and to isolated efforts to correct them. That church had in the 17th century become a creed-bound theological and sacramentarian institution, which orthodox theologians ruled with almost the absolutism of the papacy. Correctness of creed had taken the place of deep religious feeling and purity of life. Christian faith had been dismissed from its seat in the heart, where Luther had placed it, to the cold regions of the intellect. The dogmatic formularies of the Lutheran Church had usurped the position which Luther himself had assigned to the Bible alone, and as a consequence they only were studied and preached, while the Bible was neglected in the family, the study, the pulpit, and the university. Instead of advocating the priesthood of all believers, so powerfully proclaimed by Luther, the Lutheran pastors had made themselves a despotic hierarchy, while they neglected the practical pastoral work of caring for the moral and spiritual welfare of their flocks. One of the consequences, as the Pietists believed, of all this was that immorality, irreligion, and heathenish ignorance of Christianity abounded in the land, and cried to heaven against an unfaithful church. As forerunners of the Pietists in the strict sense, not a few earnest and powerful voices had been heard bemoaning the shortcomings of the church and advocating a revival of practical and devout Christianity. Amongst them were Jacob Boehme (Bemen), the theosophic mystic; Johann Arndt, whose principal devotional work on *True Christianity* is universally known and appreciated; Heinrich Müller, who described the font, the pulpit, the confessional, and the altar as the four dumb idols of the Lutheran Church; the theologian Johann Valentin Andrea, the court chaplain of the landgrave of Hesse; Schuppius, who sought to restore to the Bible its place in the pulpit; and Theophilus Grossgebauer of Rostock, who from his pulpit and by his writings raised "the alarm cry of a watchman in Sion." The direct originator of the movement was Philip Jacob Spener. Born in Alsace January 13, 1635, as a child trained in piety under the influence of a devout godmother and books of devotion recommended by her, particularly Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, he was early convinced of the necessity of a moral and religious reformation of the German church. He studied theology, with a view to the Christian ministry, at Strasburg, where the professors at the time were more inclined to practical Christianity than to theological disputation. He afterwards spent a year in Geneva, and was powerfully influenced by the strict moral life and rigid ecclesiastical discipline prevalent there, and also by the preaching and the piety of the Waldensian professor Antoine Leger and the converted Jesuit preacher Jean de Labadie. During a stay in Tübingen he read Grossgebauer's *Alarm Cry*, and in 1666 he entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a

distinct movement in the German church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversation on religious questions that arose. These meetings were largely attended, produced a great sensation, and were soon imitated elsewhere. They gave rise to the name "Pietists." In 1675 Spener published his *Pia Desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*, the public literary exposition and defence of his position and aims. In this publication Spener made six proposals as the best means of restoring the life of the church:—(1) the earnest cultivation of a more general and thorough familiarity with the Holy Scriptures by means of private meetings, *ecclesiola in ecclesia*; (2) a practical carrying out of the principle of the universality of the Christian priesthood by a participation of the laity in the spiritual government of the church and by the holding of family worship; (3) a serious laying to heart of the fact that a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) the conversion of the habit of making merely didactic, and often bitter, attacks on the heterodox and unbelievers into a treatment of them instigated by genuine affection and animated by the simple desire of doing them good; (5) a reorganization of the theological training of the universities, in such a way that young divines should be urged not only to diligence in their studies but above all to lead devout lives; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany. Although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by it, its complaint and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. He succeeded in reviving the catechetical instruction of the young in religious truth in Saxony. In Leipsic, where Scriptural exegesis had almost wholly disappeared, a society of young theologians was formed under his influence, for the learned study and devout application of the Bible. Three *magistri* belonging to that society, one of whom was August Hermann Francke, subsequently the founder of one of the noblest works of Pietism—the orphanage at Halle—commenced courses of expository lectures on the Scriptures of a practical and devotional character and in the German language, which were zealously frequented by both students and townsmen. The lectures aroused, however, the ill-will of the other theologians and pastors of Leipsic, and their promoters, charged with having slighted the established worship of the land as well as true learning, were ordered to discontinue them. Francke and his friends left the city, and with the aid of Christian Thomasius and Spener founded the new university of Halle, which became the chief home of the Pietists, and the object of the jealousy and unsparing attacks of the older universities of Wittenberg and Leipsic. The theological chairs in the new university were filled in complete conformity with Spener's proposals. The main difference between the new Pietistic school and the orthodox Lutherans was not one affecting doctrine directly, inasmuch as Spener adhered in every point to the Lutheran faith. The difference arose from his conception of Christianity as chiefly consisting in a change of heart and consequent holiness of life, while the orthodox Lutherans

of the time made it to consist mainly in correctness of doctrine. At the same time, the greater importance which he attached to the religious life and to practical godliness than to correctness of belief, and his restoration of the Bible to its place of superiority over the creeds, involved numerous possible departures from and advances beyond the Lutheranism of the 17th century. Again, the earnestness with which he had insisted on the necessity of a new birth, and on a separation of Christians from the world, led to exaggeration and fanaticism among followers less distinguished than himself for wisdom and moderation. Many Pietists soon maintained that the new birth must always be preceded by agonies of repentance, and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre, and public games, and affected a severe austerity with regard to dress, meals, and conversation. Through these extravagances a reactionary movement arose at the beginning of the 18th century, one of the most distinguished leaders of which was Loescher, superintendent at Dresden. But it was only as the opponents of Pietism gradually ceased their attacks that the movement lost its strength and by degrees handed over its vital truths and truest work to various representatives of a new and better age of the church. As a distinct movement it had run its course before the middle of the 18th century. The spirit of the school of Spener long made itself felt amongst the Protestants of north and south Germany, and particularly at Halle. Pietism could claim to have contributed largely to the revival of Biblical studies in Germany, and to have given a Biblical basis once more to theology. It also made religion once more an affair of the heart and the life, and not merely of the intellect, to which theologians had reduced it. It likewise vindicated afresh the rights of the Christian laity in regard to their own beliefs and the work of the church, against the assumptions and despotism of an arrogant clergy. It thus revived eternal elements of Christianity that had been long neglected, and was a distinct agent in preparing the way for modern advance in religion and theology. But it sprang from a temporary necessity, and, like similar phases of Christian life, lacked the philosophical and scholarly depth, the human and secular breadth, and the progressive impetus of a permanent and world-subduing religious movement.

The two most recent German writers on the history of Pietism—Heppel and Ritschl—have given a much wider meaning to the term, including under it nearly all religious tendencies amongst Protestants of the last three centuries in the direction of a more serious cultivation of personal piety than that prevalent in the various established churches, and manifesting itself particularly in the ascetic shunning of "worldly" practices. The term then embraces the Anabaptist, Moravian, Methodist, and other kindred tendencies of the religious life, which are generally regarded rather as simply related than genetically connected phenomena. Ritschl, too, treats Pietism as a retrograde movement of Christian life towards Catholicism. It is also customary with some German writers to speak of a later or modern Pietism, characterizing thereby a party in the German church which was probably at first influenced by some remains of Spener's Pietism in Westphalia, on the Rhine, in Würtemberg, and at Halle and Berlin, and which at the commencement worked to some extent on the lines of the earlier movement. The party was chiefly distinguished by its opposition to an independent scientific study of theology, its principal theological leader being Hengstenberg, and its chief literary organ the *Evangelische Kirchenzeitung*. The party originated at the close of the wars with Napoleon I.

Amongst older works on Pietism are Walch's *Historische und theologische Einleitung in die Religionsstreitigkeiten der Evangelisch-Lutherischen Kirche*, 1730; Tholuck's *Geschichte des Pietismus und des ersten Stadiums der Aufklärung*, 1865; H. Schmid, *Die Geschichte des Pietismus*, 1863; Goebel's *Geschichte des christlichen Lebens in der Rheinisch-Westfälischen Kirche*, 3 vols., 1849–50; and the subject is dealt with at length in Dörner's and Gass's *Histories of Protestant theology*. The two chief recent works which use the term in the wider sense just referred to are Heppel's *Geschichte des Pietismus und der Mystik in der reformirten Kirche*, (1879) which is sympathetic, and Ritschl's *Geschichte des Pietismus* (vol. i. only yet published, 1880) which is hostile. See also Nippold's article in *Theol. Stud. und Kritik*, 1882, pp. 347–392; and Riggenbach's article, "Pietismus," in Herzog's *Encyclopädie*, 2d ed. (J. F. S.)

PIGALLE, JEAN BAPTISTE (1714–1785), French sculptor, was born at Paris on 26th January 1714. Although he failed to obtain the Great Prize, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. His earlier work, such as *Child with Cage* (model at Sèvres) and *Mercury Fastening his Sandals* (Berlin, and lead cast in Louvre), is less commonplace in character than that of his maturer years, but his statue of Voltaire (Institut) and his tombs of Comte d'Harcourt (Notre Dame) and of Marshal Saxe (Lutheran church, Strasburg) are good specimens of French sculpture in the 18th century. He died on 21st August 1785.

See Tarbé, *Vie et œuv. de Pigalle*; Suard, *Éloge de Pigalle*; *Mélanges de littérature*; Dussieux, *Les artistes français à l'étranger*; Barbet de Jouy, *Sculptures mod. Louvre*.

PIGAULT-LEBRUN, CHARLES ANTOINE GUILLAUME, sometimes called PIGAULT DE L'ÉPINOY (1753–1835), the chief fiction writer of the first empire, and the most popular light novelist of France before Paul de Kock, was born at Calais (he is said to have traced his pedigree on the mother's side to Eustache de St Pierre) on April 8, 1753. His youth was decidedly stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by *lettre de cachet*. His first love, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mademoiselle de Salens, he married. Besides his commercial and criminal experiences, he was a soldier in the queen's guards, an actor, and a teacher of French. At the breaking out of the great war he re-enlisted and fought at Valmy. It should be said, however, that the romantic incidents of his life are differently related by different authorities, and are open to not a little suspicion. Although he had tried dramatic writing, he does not seem to have attempted prose fiction till he was forty, but from that time he was a fertile writer of novels for nearly thirty years. In his old age he took to graver work, and executed an abridgment of French history in eight volumes, besides some other work. His *Œuvres Complètes* were published in twenty volumes between 1822 and 1824. He died on July 24, 1835. Pigault's numerous novels, though still occasionally reprinted, are not much read; and none of them is much better or worse than any other. Their style is insignificant, and their morality very far from severe. But Pigault deserves the credit, such as it is, of being almost the first writer of numerous light novels calculated to hit, and which succeeded in hitting, the taste of his day. Nor was he by any means without wit. As almost the father of a kind of literature which has since developed itself enormously, and which, whatever may be its intrinsic merits, has maintained and increased its popularity for a century, Pigault-Lebrun deserves a certain place in literary history.

PIGEON,¹ French *Pigeon*, Italian *Piccione* and *Pipione*, Latin *Pipio*, literally a nestling-bird that pipes or cries out, a "Piper"—the very name now in use among Pigeon-fanciers. The word Pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to Dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon; but, as before stated (DOVE, vol. vii. p. 379), no sharp distinction can be drawn between the two, and the collective members of the group *Columbæ* are by ornithologists ordinarily called Pigeons. Perhaps the best known species to which the latter name is exclusively given in common speech² is the Wild Pigeon or Passenger-Pigeon

¹ See further under the heading POULTRY.

² It may be observed that the "Rock-Pigeons" of Anglo-Indians are SAND-GROUSE (*q.v.*), and the "Cape Pigeon" of sailors is a PETREL (*q.v.*).

of North America, *Ectopistes migratorius*, which is still plentiful in many parts of Canada and the United States, though no longer appearing in the countless numbers that it did of old, when a flock seen by Wilson was estimated to consist of more than 2230 millions. The often-quoted descriptions given by him and Audubon of Pigeon-haunts in the then "back woods" of Kentucky, Ohio, and Indiana need not here be reproduced. That of the latter was declared by Waterton to be a gross exaggeration if not an entire fabrication; but the critic would certainly have changed his tone had he known that, some hundred and fifty years earlier, Passenger-Pigeons so swarmed and ravaged the colonists' crops near Montreal that a bishop of his own church was constrained to exorcise them with holy water, as if they had been demons.¹ The rapid and sustained flight of these Pigeons is also as well-established as their former overwhelming abundance—birds having been killed in the State of New York whose crops contained undigested grains of rice that must have been not long before plucked and swallowed in South Carolina or Georgia. The Passenger-Pigeon is about the size of a common Turtle-Dove, but with a long, wedge-shaped tail. The male is of a dark slate-colour above, and purplish-bay beneath, the sides of the neck being enlivened by gleaming violet, green, and gold. The female is drab-coloured above and dull white beneath, with only a slight trace of the brilliant neck-markings.²

Among the multitudinous forms of Pigeons very few can here be noticed. A species which seems worthy of attention as being one that might possibly repay the trouble of domestication, if any enterprising person would give it the chance, is the Wonga-wonga or White-fleshed Pigeon of Australia, *Leucosarcia picata*, a bird larger than the Ring-Dove, of a slaty-blue colour above and white beneath, streaked on the flanks with black. It is known to breed, though not very freely, in captivity, and is said to be excellent for the table. As regards flavour, however, those who have been so fortunate as to eat them declare that the Fruit-Pigeons of the genus *Treron* (or *Vinago* of some authors) and its allies surpass all birds. These inhabit tropical Africa, India, and especially the Malay Archipelago; but the probability of domesticating any of them is very remote. Hardly less esteemed are the Pigeons of the genus *Ptilopus* and its kindred forms, which have their headquarters in the Pacific Islands, though some occur far to the westward, and also in Australia. Among them are found the most exquisitely-coloured of the whole Family. There may be mentioned the strange Nicobar Pigeon, *Caloenas*, an inhabitant of the Indian Archipelago, not less remarkable for the long lustrous hackles with which its neck is clothed than for the structure of its gizzard, which has been described by Prof. Flower (*Proc. Zool. Society*, 1860, p. 330), though this peculiarity is matched or even surpassed by that of the same organ in the *Phœnorhina goliath* of New Caledonia (*Rev. de Zoologie*, 1862, p. 138) and in the *Carpophaga latrans* of Fiji. In this last the surface of the epithelial lining is beset by horny conical processes, adapted, it is believed, for crushing the very hard fruits of *Onocarpus vitiensis* on which the bird feeds (*Proc. Zool. Society*, 1878, p. 102). The modern giants of the group, consisting of about half a dozen species of the genus *Goura* and known as

Crowned-Pigeons, belong to New Guinea and the neighbouring islands, but want of space forbids further notice of their characteristics, of which the most conspicuous are their large size and the reticulated instead of scutellated covering of their "tarsi."

A very distinct type of Pigeon is that represented by *Didunculus strigirostris*, the "Manu-mea" of Samoa, still believed by some to be the next of kin to the Dodo (vol. vii. p. 321), but really presenting only a superficial resemblance in the shape of its bill to that effete form, from which it differs osteologically quite as much as do other Pigeons (*Phil. Transactions*, 1869, p. 349). It remains to be seen whether the Papuan genus *Otidiphaps*, of which several species are now known, may not belong rather to the *Didunculidæ* than to the true *Columbidæ* (see ORNITHOLOGY, vol. xviii. p. 46).

At least 500 species of Pigeons have been described, and many methods of arranging them suggested. That by Garrod (*Proc. Zool. Society*, 1874, pp. 249–259) is one of the most recent; but, for reasons before assigned (vol. xviii. p. 40), it is not satisfactory. Temminck's great work on the group with its continuation by M. Florent-Provost, already mentioned (vol. xviii. p. 11), is of course wholly out of date, as also Selby's more modest *Natural History of the Columbidae* (forming vol. ix. of Jardine's *Naturalist's Library*). Schlegel's catalogue of the specimens contained in the museum at Leyden (*Museum des Pays-Bas*, livr. 10, 1873) contains much useful information, but a new monograph of the Pigeons, containing all the recent discoveries, is much wanted.

(A. N.)

PIGMENTS are coloured powders which, when mixed with oil, water, or other fluids, in which they are insoluble, form paints. They are distinguished from dyes and washes by their entire insolubility in the media in which they are mixed, whereas dye-stuffs are tinctorial substances applied in solution. Insoluble colours, when used in printing textile fabrics, are distinguished as pigment colours. The sources of materials available as pigments are numerous; many are native coloured earths, others are separated from native metallic compounds and other mineral substances; a large number are artificially prepared from inorganic—principally metallic—sources; an important class consist of animal and vegetable colouring principles, forming with earthy bodies insoluble powders called lakes; and the dye-stuffs artificially obtained from organic sources are also similarly utilized. In fact all substances coloured or neutral, capable of being presented in the form of impalpable powder, which at the same time are insoluble and unalterable under ordinary atmospheric influences, may be regarded as possible pigments. But there are many qualities practically essential in a pigment which limit the range of available substances. A consideration of the first importance is the "body" or covering power of a pigment,—that is, the property of fully covering and concealing with an opaque coating the surface over which it is spread. It is also important that the material should work well in, and be unaffected in appearance and constitution by the medium with which it is made into a paint, and that it should spread in an even uniform coat, which should dry well and quickly in the air and adhere firmly to the surface to which it is applied. When dry it should possess durability and resist change under the action of weather and other influences to which paint is exposed. These are the principal qualities requisite in paints in their important function of preservative coatings for the surfaces to which they are applied. On their artistic side, as decorative and pictorial materials, pigments should possess purity and brightness of colour with intensity of tinting power, capacity for mixing or coming into contact with other colours without injuriously

¹ *Voyages du Baron de la Hontan dans l'Amerique septentrionale*, ed. 2, Amsterdam, 1705, vol. i. pp. 93, 94. In the first edition, published at The Hague in 1703, the passage, less explicit in details but to the same effect, is at p. 80. The author's letter, describing the circumstance, is dated May 1687.

² There are several records of the occurrence in Britain of this Pigeon, but in most cases the birds noticed cannot be supposed to have found their own way hither. One, which was shot in Fife in 1825, may, however, have crossed the Atlantic unassisted by man.

affecting these or being themselves deteriorated, and permanence and unalterability of tone after long exposure.

Pigments being so numerous and so diverse in their origin, the industries connected with their production and preparation are of necessity varied in character. Many of the substances employed being used in large quantities in other important industrial relations, as well as for paints, are manufactured on a large scale and constitute the basis of considerable chemical industries, as, for example, the manufacture of white lead, Prussian blue, ultramarine, the chrome materials, &c. In other cases the materials require no preparation other than that given to them by the paint-grinder or the artists' colourman, according to the purpose for which the substances are to be prepared.

The colour trade embraces two distinct departments:—that of the paint-grinder, who manufactures and compounds the pigments used by artisans, house-painters, and paper-stainers; and that of the artists' colourman, who prepares and supplies the finer, more brilliant, and extensive assortment of pigments used for artistic purposes. The pigments employed for pottery painting and glass and enamel work are a special class of preparations to suit the requirements of these trades. Leaving out of account the chemical reactions involved in preparing raw materials, the ordinary manufacturing operations connected with the preparation of painters' colours are simple, and consist essentially of a careful system of grinding. Formerly, when painters ground their own colours, a stone slab and muller formed the entire apparatus; but now, when paint-grinding has become a separate industry, efficient machinery has been devised for grinding and its collateral operations. Bulky and rough colours such as whiting and common ochres are dry-ground under heavy edge stones which revolve in a strong iron bed. Ordinary dry colours requiring to be pulverized with more care are mixed to a thin cream with water, which is fed into and ground principally between a pair of millstones dressed and mounted like the ordinary horizontal stones of a flour mill, but smaller in diameter. For fine colours the pigment so ground is levigated, or floated into a vat in which the heavier particles sink, and the lighter, more finely divided portion is run into another vessel at a lower level, where it is deposited as a fine sediment. The sediment is dried in a uniformly heated stove, and when thoroughly dry is again pulverized under a pair of edge stones, and sifted or winnowed; so treated it is ready for use as dry colour. The greater proportion of the white lead and the other common oil paints are ground in oil. For this purpose the raw material is mixed in a machine with oil (sometimes boiled) to the consistence of a stiffish paste, and in this state it is ground in horizontal paint millstones, after which it requires no further preparation than the necessary thinning with oil when to be used for painting. There are many varieties of apparatus used for grinding both dry and oil colours.

The artists' colourman grinds his pigments with much greater labour, and selects his materials in a more careful manner, than is necessary in the case of the ordinary paint-grinder. Pigments for artistic painting in oil are ground in that medium to a definite consistency, and are put up for use in convenient compressible tubes of tin. For water colours the pigments are prepared principally in the form of small indurated cakes or as "moist colours" contained in small porcelain dishes. Water colours may also be obtained thin in tin tubes like oil colours, or as "pastilles," which are thin round cakes intermediate in condition between cake and moist colours.

In enumerating the principal commercial pigments it is usual and convenient to classify them according to their tints. They are not, as a rule, definite chemical com-

pounds: many indeed are mixed substances prepared by processes and according to recipes known only to their makers; and, while the same commercial name is frequently given to substances quite dissimilar in character, the confusion is further increased by applying many different titles to substances which are practically identical. Thus white lead is known by at least a dozen names, and distinct and even conflicting qualities are by authorities attributed to this one substance under its various aliases.

It would be impossible to catalogue all the paints met with in commercial lists, and it would serve no good purpose to enumerate the whole of the pigments which might be and are occasionally used. Premising that details regarding many of the substances will be found under the heading of the metals, &c., whence they are derived, we shall here simply classify, according to their colour, the principal well-recognized pigments of commerce, adding brief remarks regarding each class.

WHITE PIGMENTS.—The whites are the most important pigments, used by painters, forming as they do the basis or body of nearly all paints, excepting only certain dark hues. Good available whites are limited in number, and all of real importance are included in the following list:—white lead, a carbonate of lead (chiefly); zinc white, oxide of zinc, called also Chinese white; antimony white, oxide of antimony; fixed white, sulphate of baryta; "silicate" white, sulphate of baryta, or strontia and sulphide of zinc; mineral white, powdered gypsum (with alumina it forms satin white); chalk or whiting carbonate of lime and china clay, silicate of alumina.

White Lead (see LEAD, vol. xiv. p. 378) is the most important of all pigments, and forms the basis of nearly all ordinary oil paints, which, when coloured, consist of white lead tinted with the necessary coloured pigments. It possesses the greatest amount of body or covering power, and works beautifully in oil, with which it partially combines, drying as a hard homogeneous adherent plaster. On the other hand it is a most poisonous body, very injurious to the persons connected with many of the processes by which it is prepared. As an oil colour it darkens gradually in an atmosphere containing traces of sulphur; it cannot be used at all as a water or distemper colour; and it acts injuriously on the colour of several important pigments. Notwithstanding these drawbacks no white has yet been made that can compete with white lead, although paint manufacturers go far to provide a substitute by adulterating it to such an extent that the white lead frequently bears only a small ratio to the adulterant. Baryta white is the ordinary adulterant, and among respectable manufacturers the intermixture is a well-understood fact, and the relative proportions of white lead and baryta are regulated by a series of grades passing from "genuine" to No. 5 or No. 6 white lead. Many efforts have been made to substitute for ordinary white lead lead carbonates made by other processes, and other lead salts such as the oxychloride (Pattinson's), sulphate, tungstate, antimoniate, &c.; but none of these has proved permanently successful.

Zinc White.—Next in importance to white lead, is an oxide of zinc prepared by the sublimation and combustion of metallic zinc. The pigment is deficient in covering power and it dries but slowly when mixed with oil. On the other hand it is not injurious to health, its purity of tone is not affected by sulphurous air, it does not affect tints added to it or with which it comes in contact, and it can be used in water as well as in oil. Like white lead it is very much adulterated, and generally with the same agent—baryta white.

Baryta White plays an important independent part as well as acting so extensively as a sophisticator of other pigments. It is prepared by grinding to a fine powder the pure white native sulphate of baryta (heavy spar), and the same substance artificially prepared is known as permanent white or *blanc fixe*. The artificial preparation is much superior, as a pigment, to the powdered spar; but both are deficient in body, notwithstanding which they are of great value to paper-stainers and for distemper painting.

Under the name of *Charlton White* or silicate paints, Mr J. B. Orr prepares a range of white paints which have come into extensive use. The pigment as originally prepared under Mr Orr's patent of 1874 consisted of an intimate mixture of artificial sulphate of baryta and sulphide of zinc in certain proportions, made by the double decomposition of solutions of barium sulphide and sulphate of zinc. In 1881 a patent was secured by Mr Orr for a combination in which strontia takes the place of baryta. It is claimed for these pigments that they possess body greater than white lead, that they are non-poisonous, and that with certain modifications in the manufacture they can be made quite as valuable for distemper painting as for oil colours.

The oxides of antimony, tin, bismuth, &c., form white pigments; but these possess no peculiarities which render them valuable for painters' use. The carbonate of lime, more or less pure and in various degrees of pulverulence under several names, such as *Chalk White*, *Paris White*, *Whiting*, &c., is very extensively used in distemper work for walls, roofs, &c., and in paper-staining, occupying in these relations the important place held by white lead in oil painting. Mineral white or satin white consists of powdered gypsum and alumina, a preparation very largely used by paper-stainers for their glossy satin bodies. There are several other white earths of relatively little importance as pigments.

BLUE PIGMENTS.—The list of blue colours of real importance is not extensive, comprising, as principal items, ultramarine, Prussian blue, the cobalt blues, and indigo. The following list embraces the names and varieties ordinarily recognized in commerce:—ultramarine (native), powdered lapis lazuli; ultramarine (artificial), silicates of alumina and soda with sulphide of sodium; Prussian blue, cyanide of iron; Paris blue, modified Prussian blue; Antwerp blue, fine Prussian blue; smalts, a cobalt glass; azure blue, a preparation of smalts; cobalt or Thenard's blue, sub-phosphate of cobalt; ceruleum, stannate of cobalt and sulphate of lime; mountain blue, native carbonate of copper; lime blue, carbonate of copper and lime; Verditer or Bremen blue, hydrated oxide of copper; indigo from species of *Indigofera*; indigo carmine, preparation of indigo.

Apart from the important colours **ULTRAMARINE**, **PRUSSIAN BLUE**, and **INDIGO**, separately noticed, these blues, which are not of much value for painters, owe their colour principally to cobalt and copper. The principal cobalt colour is *Smalts*, called also strewing smalts, cobalt glass, zaffre, Saxony blue, &c. It is prepared by smelting together the mineral arsenide of cobalt, pure sand, and carbonate of potash into a glass. The molten glass is cast into cold water, then ground fine and levigated. Smalts is chiefly available for distemper and fresco painting, and is not much used as an oil colour. *Azure Blue* is generally recognized as a preparation of smalts, but the name is given to several compounds. *Ceruleum* is a light blue colour of durable quality with a greenish tinge, consisting of a combination of cobalt oxide with stannic acid; and *Cobalt Blue*, the subphosphate of cobalt, a colour discovered by Thenard, possesses a purple tinge. Carbonate of copper, either in the form of the mineral azurite or artificially prepared, is a principal source of the copper blues, which, however, possess little value as pigments owing to their tendency to blacken under exposure. *Blue Verditer*, a greenish blue which passes into green verditer, is a hydrated oxide of copper.

YELLOW PIGMENTS.—The following list includes the ordinary yellow colours of commerce:—ochres and sienna earth, native earths tinted with iron; Mars yellow, hydrated ferric oxide; chromes, chromates of lead and other metals; massicot, protoxide of lead; Naples yellow, antimoniate of lead; mineral yellow, basic chloride of lead; aureolin, nitrate of potassium and cobalt; cadmium yellow, sulphide of cadmium; orpiment, trisulphide of arsenic; Indian yellow, urio-phosphate of calcium; gamboge, resin of *Garcinia*; Dutch pink, a vegetable lake; yellow lakes.

Of these colours the more important are the ochres and the various combinations containing chromium. The *Yellow Ochres* are native earths coloured with hydrated ferric oxide, the brownish yellow substance that colours, and is deposited from, highly ferruginous water. These ochres are of two kinds—one having an argillaceous basis, while the other is a calcareous earth, the argillaceous variety being in general the richer and more pure in colour of the two. Both kinds are widely distributed, fine qualities being found in Oxfordshire, the Isle of Wight, near Jena and Nuremberg in Germany, and in France in the departments of Yonne, Cher, and Nièvre. The original colour of these ochres can be modified and varied into browns and reds of more or less intensity by calcination. The high heat expels the water of hydration from the iron oxide, changing it into red ferric oxide. The nature of the associated earth also influences the colour assumed by an ochre under calcination, aluminous ochres developing red and violet tints, while the calcareous varieties take brownish red and dark brown hues. The well-known ochre *Terra da Sienna* which in its raw state is a dull-coloured ochre, becomes when burnt a fine warm mahogany brown hue highly valued for artistic purposes. Yellow ochres are also artificially prepared—*Mars Yellow* being either pure hydrated ferric oxide or an intimate mixture of that substance with an argillaceous or calcareous earth, and such compounds by careful calcination can be transformed into *Mars Orange*, *Violet*, or *Red*, all highly important, stable, and reliable tints. The metal chromium owes its name to the intense coloration produced by the combination of its oxide, chromic acid, with various metals and alkaline earths. Several of these salts are soluble, but those which form pigments are insoluble compounds. The principal chrome pigments—the various shades of lemon and yellow chrome deepening to orange tints—are composed of the neutral chromate of lead, the difference of hue depending on the greater or smaller proportion of lead used in the preparation. The basic chromate of lead has a

deep orange colour passing into the minium-red-like hue of chrome red. *Strontia Chrome*, the chromate of strontium, is a pale lemon pigment of fine quality and permanence. With zinc, chromic acid forms two combinations, neutral and basic, both possessed of an intense yellow colour; and chromate of barium also furnishes a useful yellow colour. Lead itself, without chromium, is the basis of several valuable yellows. *Massicot*, the protoxide of lead, is a clear yellow pigment deficient in body. *Naples Yellow*, a colour highly esteemed by early artists, is an antimoniate of lead which in early times was obtained from native sources; and *Mineral Yellow* is an oxychloride of lead. The sulphide of cadmium forms the fine durable *Cadmium Yellow*, a colour now much appreciated for artistic use. The arsenical yellow, *Orpiment*, is now little used as a pigment, although formerly, under such names as *King's Yellow*, *Imperial Yellow*, and *Chinese Yellow*, it was held in high esteem by artists. *Aureolin*, a nitrate of potassium and cobalt, is a colour of recent origin which has come into high favour among artists. *Indian Yellow* is a colour of animal origin of no permanence, and *Gamboge* is a gum resin yielded by trees of the genus *Garcinia*, principally employed as a water colour. The yellow lakes are comparatively unimportant, but some, known, rather absurdly, as *Dutch*, *English*, or *Italian Pink*, are largely used in paper-staining.

RED PIGMENTS embrace two distinct series of substances—the reds of inorganic origin, and red lakes obtained from animal and vegetable colours. The principal commercial varieties are as follows:—rouge, Turkey red, and Indian red, red ferric oxide; Venetian red, ochreous ferric oxide; ochres, earths coloured by ferric oxide; vermilion and cinnabar, sulphide of mercury; antimony vermilion, red sulphide of antimony; Derby red, a form of chrome red; red lead or minium, red oxide of lead; chrome red, basic chromate of lead; realgar, bisulphide of arsenic; madder lake, alizarin and alumina; madder carmine, preparation of alizarin; carmine lake, cochineal red and alumina; carmine, preparation of cochineal; wood lakes, from various red dyewoods.

The principal mineral reds owe their colour to oxides of iron and to compounds of mercury. The reds due to iron are closely allied to the yellow ochres and other ferruginous pigments. As already explained in connexion with these yellows, tints passing through orange to deep purple reds are obtained by calcination of yellow hydrated ferric oxide, and in this way a great variety of ruddy and red tints are prepared. The proportion of ferric oxide in these compounds ranges from pure oxide to combinations in natural ochres containing not more than 2 or 3 per cent. of iron. *Rouge* or *Mars Red*, *Crocus*, *Indian Red*, and *Turkey Red* are all pure ferric oxide, varying in depth of tint from having undergone different degrees of calcination, or from being made from different artificial or natural sources. The other iron reds are all of the nature of ochres—some of them, such as *Venetian Red*, being artificial compounds. These reds form exceedingly useful durable colours which do not injuriously affect the tints with which they are associated. Of red colours from mercury, *Cinnabar* and *Vermilion* are the most important, the former being the native and the latter an artificial sulphide of mercury (see **MERCURY**, vol. xvi. p. 34). Vermilion is one of the most pure, brilliant, solid, and durable of all colours. Its beauty is largely affected by the smoothness of the powder to which it is reduced, and in this respect that obtained from China is of the highest excellence. Being a costly pigment, vermilion is freely adulterated with other reds, a fraud easily detected by the perfect volatility of the genuine substance. From mercury combined with iodine is prepared a pigment of unequalled vivacity and brilliance, *Iodine Scarlet*, but unfortunately as fugitive as it is bright, and consequently not available for work requiring permanence. The principal red colour from lead is *Minium* or *Red Lead*, a pigment of great antiquity obtained as a product of the oxidation of massicot, or by the calcination and oxidation of white lead. It is orange red in colour, of good opacity and body, but it has the fault of white lead and lead colours generally, blackening in contaminated air and injuring colours with which it comes in contact. By itself it is a valuable paint for first coating exposed iron surfaces to prevent their oxidation, and it is an excellent dryer, on which account it is much used in preparing boiled oil for painters. *Chrome Red*, a basic chromate of lead known also as *Persian* or *Derby Red*, is a brilliant pigment ranging in tone from orange to a deep vermilion hue. It is obtained by precipitating a solution of acetate of lead with bichromate of potash, with the addition of more or less of caustic potash or soda,—the proportion of the latter addition determining the depth of resultant tone. *Antimony Vermilion* is the red variety of the sulphide of antimony which, as found in nature (stibnite), is a dark grey body with metallic lustre. This, when fused and kept some time at a high heat and suddenly cooled, by allotropic modification becomes a fine vermilion red. The colour is artificially prepared by acting on solutions of the butter of antimony (antimony chloride) with hyposulphite of soda or lime. It is a colour of excellent purity and body as a water colour, but unfortunately it becomes brown by exposure. The lakes form a numerous and important class of red pigments. A lake is a combination of a colour of organic origin with a metallic oxide or salt,

commonly with alumina. Originally all lakes were red colours, the name being derived from the lac insect *Coccus lacca*, the colouring matter of which forms the lake now known as *Lac Lake*. But lakes of any colour or tint are now made. The most important lake pigment is *Madder Lake*, a compound of alumina and the tinctorial principle of madder root, *Rubia officinalis*, but now made with artificial alizarin. *Scarlet* or *Carmine Lake* has cochineal for its colour basis, and there are corresponding lakes from lac, kermes, &c. *Wood Lakes* coloured with several of the red dyewoods have little durability, but they are nevertheless largely used by paper-stainers. *Carmine*, a colouring matter from cochineal, and *Madder Carmine* or *Field's Carmine*, from madder, are exceedingly brilliant colours; but the first of them is of a fugitive character.

GREEN PIGMENTS form an extensive group embracing two sections:—(1) simple greens, in which green is a primary inherent or natural colour; and (2) compound greens, made up of intimate mixtures of blue and yellow pigments. The latter class it is obvious are capable of indefinite modification by simply varying the proportions of the compound ingredients. The following list embraces the principal commercial greens:—Brunswick green, oxychloride of copper; malachite green or mountain green, hydrated carbonate of copper; verdigris, sub-acetate of copper; verditer or Bremen green, hydrated oxide of copper; Scheele's green, arsenite of copper; Schweinfurt green, mixed acetate and arsenite of copper; emerald green, a variety of Schweinfurt green; mineral green, mixed copper oxide and arsenite; chrome green, oxide of chromium; Guignet green or veridian, hydrated oxide of chromium; Cassel green, manganate of baryta; cobalt green, oxides of cobalt and zinc; ultramarine green, modified artificial ultramarine; Veronese earth or terra verde, a form of ochre; green lakes.

The greater proportion of these greens are copper compounds—the most brilliant of them containing also arsenic. They are all poisonous colours, the latter especially being dangerous poison; and there can be no doubt that their free use in wall papers, the colouring of toys, artificial flowers, &c., is frequently the source of dangerous disease and even death. *Brunswick Green*, the most important non-arsenical green, is an oxychloride of copper, but factitious Brunswick greens are not uncommon. *Scheele's Green*, the arsenite of copper, and *Schweinfurt Green*, mixed arsenite and acetate of copper, are very powerful and brilliant colours. These copper greens all blacken in foul gases and when mixed with oil, and thus, although they possess great body, they are much more useful to the paper-stainer than the painter. The sesquioxide of chromium both water-free and hydrated, prepared in various ways, forms important stable green colours which resist atmospheric influences; and chromium is further the basis of several other green colours, which, however, are not of importance. *Cobalt Green*, a mixed oxide of cobalt and zinc, discovered by the Swedish chemist Rinman, is a valuable and durable but expensive colour. *Cassel Green*, called also *Rosenstiehl's Green*, is a fine innocuous pigment made by melting together sulphate of baryta and oxide of manganese, and carefully washing the resulting mass in water. *Verona Green* or *Terra Verde*, a natural celadon green highly valued by artists for permanence, is a mixed earthy body coloured by ferrous oxide, and *Ultramarine Green*, also a stable body, is an intermediate product of the manufacture of ultramarine blue.

BROWN PIGMENTS.—Many of the painters' browns are simply tints obtained by mixture. In the case of simple pigments the shades pass by fine gradations into yellows and reds, so that the limits of classification are not well defined. The following are generally classed as pure browns:—umber, silicate of iron and manganese; brown ochres, called Mars brown, iron brown, &c., native and artificial earths; Vandyke brown and Cologne or Cassel brown, peaty ochres; purple brown, ferric oxide; Spanish brown or tiver, a brown iron ochre; bistre, washed beechwood soot; sepia, secretion of cuttle-fish; brown lake; asphaltum, natural and artificial pitch.

Iron and manganese, separately or combined, earthy or pure, are the sources of the principal brown pigments. Some of them are intermediate products between yellow ochres and red ochres by calcination of the yellow, and, as they are ochreous in their nature, their colours may be heightened or otherwise modified by calcining. Thus *Umbre*, which properly is a hydrated silicate of manganese and iron, is brightened in colour by calcination into *Burnt Umber*. The finest umber comes from the island of Cyprus, and is known as *Turkey umber*. Large quantities also of "English" umber are mined in Devonshire and Cornwall. *Real Vandyke Brown*, a very celebrated pigment, ought to be a kind of bituminous peaty earth of a fine rich semi-transparent colour, allied to which are *Cologne* and *Cassel Earth*. But under the name Vandyke brown pure ferric oxide and ferruginous earths of a clear brown hue are also sold. *Cappagh Brown* is a peaty earth coloured by manganese, found at Cappagh near Cork, Ireland, and is a valuable artists' colour, as is also *Bistre*, a brown washed from the soot of beechwood. *Sepia*, a much valued warm brown, is a substance secreted by the cuttle-fish, *Sepia officinalis*, which emits it to cloud the water for concealing its whereabouts when alarmed.

BLACK PIGMENTS form a numerous class of bodies, though those in common use are easily enumerated. They appear in commerce principally under these names:—vegetable black, carbonized vegetable matter; lamp black, soot of oils and fats; Indian ink, preparation of lamp black; ivory black, carbonized ivory and bone; bone black, carbonized bone; blue black, washed wood charcoal; charcoal black, carbonized wood; black wad, a native oxide of manganese; black lead, a form of carbon; tar, from distillation of organic substances.

Most of these blacks owe their colour to carbon. From the charring of vegetable substances are prepared *Charcoal Black*, *Blue Black*, and *Vegetable Black*, but these take many names according as they are prepared from carbonized wood, twigs of the grape vine, peach and other fruit stones, cork, the lees of wine, &c. *Bone* and *Ivory Blacks* again are carbonized animal substances, principally bones, which when skilfully burned yield dense durable blacks. *Lamp Black* of the best quality is the soot deposited from the imperfect combustion of oils and fats, and the soots of resin and tar are also collected and used under this name. *Indian Ink* (see vol. xiii. p. 80) is a form under which lamp black of the finest quality occupies an important position among pigments. Of the other blacks *Tar* is the most important owing to its extensive use as a preservative and antiseptic coating.

Several pigments are prepared on account of special properties apart from the protective and decorative purposes for which ordinary paints are applied. Among such may be mentioned Balmain's luminous paint, a preparation in oil or water of certain of the phosphorescent sulphides. Objects coated with this material have the property of continuing to emit light in dark situations for some time after they have been exposed in daylight or to high artificial light. The luminous paint has been proposed for coating buoys, signals, public notice boards, clock and watch dials, playing balls, match boxes, &c., but it has not come into extensive use. Powdered asbestos has been introduced as a fire-proof paint for wood; but all common paints applied as distemper colour are equally fire-proof in the sense that they themselves are incombustible, and when they coat wood thickly they offer great resistance to an incipient fire, and even retard combustion under very high heat. Numerous anti-fouling compositions for the painting of ships' sides and bottoms and anti-corrosive, inoxidizable, damp-proof, and water-proof paints have been patented, some of which are in extensive use. (J. P. A.)

PIKE, freshwater fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (*Esocidae*) of Soft-rayed Fishes. They are readily recognized by their elongate compressed body covered with small scales, a long head, long and spatulate snout, and very large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backwards or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the

European Pike (*Esoc lucius*).

tail, thus greatly increasing the propelling power of the fish, and, although pike are bad swimmers and lead rather a sedentary than a roving life, they are excelled by no other freshwater fish in rapidity of motion when, by a single stroke of the tail, they dash upon their prey or dart out of reach of danger. In the Old World one species only is known (*Esoc lucius*), which prefers lakes and sluggish reaches of rivers to strong currents or agitated waters. Its eastward range in northern Asia is not known; it extends into Lapland in the north and into central Italy

and the vicinity of Constantinople in the south, but is absent in the Iberian Peninsula. The European species occurs also in North America, and is common in the eastern United States southwards to northern Ohio. But North America is tenanted by other species of pike besides, of which the largest is the Muskelunge or Maskinonge of the Great Lakes (*Esox nobilior*); it commonly attains to the large size which is exceptionally recorded of *Esox lucius*. The other American pike are of smaller size, and generally named "Pickerel"; but opinions as to the distinction of the species differ widely among American ichthyologists. The European pike, like its brethren, is the most voracious of freshwater fishes; it probably exceeds the shark, to which it has been compared by many writers, in the relative quantity of food it consumes. Ponds would soon be depopulated but for its cannibal propensities, no pike being safe from another of its own kind large enough to swallow it. To the young of water-fowl pike are most destructive, and large specimens will seize rats or rabbits when they take to the water, and are said to attack even foxes and small dogs. Individuals of from forty to fifty pounds are not scarce, but captures of much larger ones are on record. Pike are wholesome food, and much esteemed in inland countries,—the smaller (of 20 to 24 inches in length) being preferred to the larger individuals. They are prolific, and not easily exterminated in a water in which they have been once allowed to spawn. According to season and climate they spawn in April or May, and sometimes as early as February.

PIKE-PERCH (*Lucioperca*), freshwater fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. As indicated by the name, these fishes show some slight resemblance to the pike in their elongate body and head, and like that fish they are most dangerous enemies to other freshwater fishes. Their acclimatization therefore in waters intended for the culture of valuable food fishes is not advisable, though they compensate in some measure for their destructiveness by the excellent flavour of their flesh. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*); strange to say, it is absent in the system of the Rhine. It prefers the quiet waters of large rivers and clear deep lakes, in which it reaches a weight of twenty-five or thirty pounds; it does not thrive in small and confined waters. The second European species (*Lucioperca wolgensis*) is limited to rivers in southern Russia and Hungary. In North America several pike-perches have been described, but in the most recent works only two are distinguished, viz., *Lucioperca americana*, which grows to a weight of twenty pounds, and the much smaller *Lucioperca canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PILATE,¹ PONTIUS, the fifth Roman procurator or "governor" (ἐπίτροπος, ἡγεμὼν) of Judæa, Samaria, and Idumæa, succeeded Valerius Gratus in 26 A.D. By rank he was a Roman eques, possibly of Samnite extraction; his official appointment he owed to the influence of Sejanus. His ordinary residence as procurator was at Cæsarea, the capital, but from time to time he visited Jerusalem, especially at the greater feasts, and on these occasions he had his *bema* in the magnificent palace of Herod the Great, hence called the *prætorium*. Apart from the supreme (to him, likely enough, most trivial) incident in

his life ("suffered under Pontius Pilate") the few facts that are known of him indicate a somewhat exceptional recklessness about awakening Jewish fanaticism, and unscrupulousness as to the means used in quelling its manifestations. Not long after his appointment he allowed his soldiers to carry their eagles and other insignia to Jerusalem, and did not give way until an excited mob had stormed for five whole days and nights around his palace at Cæsarea. At a later date, in order to provide for the completion of his aqueduct for bringing water to the city from the "Pools of Solomon," he appropriated funds from the Corban or sacred treasury; but, profiting by his former experience, when this conduct was resented by the populace he caused some of his soldiers, disguised as Jewish citizens but armed with staves and daggers, to mingle in the crowd, when many casual spectators as well as rioters were trampled to death. For having hung up in Herod's palace certain gilt shields dedicated to Tiberius he was in vain remonstrated with by the Jews, but Tiberius, on being appealed to, ordered their transference to the temple of Augustus at Cæsarea. Of the circumstances under which he "mingled the blood" of certain Galileans "with their sacrifices" nothing is known; but his cruelty in causing a number of Samaritans to be attacked and massacred when assembled on Mount Gerizim led to a complaint being lodged with Vitellius the legate of Syria, and ultimately to his being deprived of his office early in 36 A.D. According to Eusebius (*H. E.*, ii. 7) he was banished to Vienne in Gaul, where various misfortunes caused him at last to commit suicide; the *Chronicle* of Malalas alleges, with less probability, that he was beheaded under Nero. Later legend (see, for example, the apocryphal *Mors Pilati* mentioned below) has a good deal more to say: his suicide was anticipatory of Caligula's sentence; the body was thrown into the Tiber and there caused disastrous tempests and floods; it afterwards produced similar effects in the Rhine at Vienne, and finally had to be consigned to a deep pool among the Alps. Local tradition points to a little tarn on Mount Pilatus near Lucerne; if anything is thrown into it the water is forthwith strangely agitated. The devil takes the body from the water on Good Fridays and sets it on a throne where it goes through the gesture of washing its hands. The fact that Pilate allowed Jesus to be crucified is by no means out of keeping with what we know of his indifference to the claims alike of justice and of mercy; that he obviously wished to spare him if this could be done without too much inconvenience to himself has, however, gained him in some quarters very generous recognition; thus Tertullian speaks of him as "jam pro sua conscientia Christianum," the Copts regard him as a martyr, and the Abyssinian Church has given him a place in its calendar (June 25). This view is reflected in the spurious *Paradosis Pilati*. Pilate's wife, known to tradition as Procla or Claudia Procula, is represented as having been a proselyte of the gate and a secret disciple of Jesus. She is commemorated as a saint in the Greek Church (Oct. 27).

There is a considerable body of apocryphal literature connected with the name of Pilate. The *Acta Pilati*, which forms part of the *Evangelium Nicodemii*, gives a copious account of the trial of Jesus, intermingled with legendary details of uncertain and very unequal value. It exists in a variety of texts, but in substance is supposed with most probability to date from about the middle of the 2nd century, and to be the work of a Jewish Christian, written for Jews. The *Epistola Pilati*, of which there are two differing forms, contains what purports to be Pilate's account to Tiberius of the resurrection of Jesus. The *Paradosis Pilati* relates his trial, condemnation, and execution at the emperor's command; Pilate appeals in prayer to Jesus, and, along with Procla his wife, is received as a true penitent into the number of the faithful. The *Mors Pilati* relates the circumstances of his suicide, the casting of his body into the Tiber, its removal to Vienne (explained as "Via Gehennæ"), and the final disposal of it at "Losania." For all

¹ I.e., *Pilatus*, either derived from *pilum*, and thus analogous with the surname *Torquatus*, or a contraction of *pileatus*. The *pileus* was the badge of manumitted slaves, and if this etymology be accepted, the name probably indicates that Pilate was a *libertus*, or the descendant of a *libertus*, of a member of the Samnite gens of the Pontii.

these apocryphal writings see Tischendorf's *Evangelia Apocrypha* (1868).

PILCHARD (*Clupea pilchardus*), a fish of the herring family (*Clupeidae*), abundant in the Mediterranean and on the Atlantic coasts of Europe, northwards to the British Channel. Sardine is another name for the same fish, which on the coast of Brittany and Normandy is also called *Célan* or *Céléren*. It is readily distinguished from the other European species of *Clupea* or herrings. The operculum is sculptured with ridges radiating and descending towards the suboperculum; the scales are large, about thirty along the lateral line, deciduous; the ventral fins are inserted below, or nearly below, the middle of the base of the dorsal fin; the dorsal fin has seventeen or eighteen, the anal from nineteen to twenty-one rays. A small blackish spot in the scapular region is very constant, and sometimes succeeded by other similar marks. There are no teeth on the palate; pyloric appendages exist in great numbers; the vertebrae number fifty-three. The pilchard is one of the most important fishes of the English Channel (see article FISHERIES, vol. ix. p. 253 sq.). It spawns at a distance from the shore, and, according to Couch, the spawn has been seen to extend several miles in length, and a mile or more in breadth floating on the surface of the sea, of the thickness of brown paper, and so tough as not to be readily torn in pieces. The spawning takes place at two periods of the year, viz., in April or May, and again in the early part of autumn; but it is not probable that the same individuals or shoals spawn twice in the same year. When commencing their migrations towards the land, the shoals consist of countless numbers, but they break up into smaller companies in close vicinity to the shore. Pilchards feed on minute crustaceans and other animalcules, and require two or three years before they attain their full size, which is about 10 inches in length. On the Pacific coasts of America, in New Zealand, and in Japan a pilchard occurs (*Clupea sagax*) which in its characters and habits is so similar to the European pilchard that its general utilization is deserving of attention, and there is every reason to believe that New Zealand could produce its own sardines and fumadoes. Immense shoals are reported to visit the east coast of Otago every year in February and March.

PILES. See HÆMORRHOIDS.

PILGRIMAGE. The word Pilgrimage (derived from the Latin *peregrer*, i.e., *per-ager*, "one who traverses a region," through the intermediate forms *peregrinus*, *pellegrino*, *pelegrin*) denotes the act of journeying to some place esteemed sacred, for the purpose of discharging a religious obligation, or to obtain some supernatural assistance or benefit. The practice is common to many religions, and mounts back to prehistoric ages. It is ultimately traceable to the nature of tribal religion, in its early form of worship of a deity regarded as purely local in the sphere of his special influence. As community in religious acts was one of the principal ties between members of the same tribe, to the exclusion of outsiders, it would naturally become the rule, and then the duty, of the tribesmen to present themselves at recurrent intervals at the sanctuary of their tribal god. As they scattered away from their own settlement, and became travellers or sojourners amongst aliens, the belief that they were in some sense cut off from the protection of their tribal deity, and subjected to the influence of others in whose worship they had no share, would induce visits from a distance to the seat of their own religion, not merely for the purpose of keeping up their tribal relations, but to propitiate a power which perhaps could not hear supplications addressed from a distance, and would in any case be more ready to hear and answer prayers made in his own special shrine, attended with the appro-

priate rites performed by his own body of ministers. This latter consideration would operate even in the case of cults directed to the Sun-God, the Moon-Goddess, and the planetary bodies, which could hardly be regarded as localized within earthly boundaries, but might well be supposed more placable in shrines of exceptional splendour and sanctity, officered by a trained and numerous priesthood. And wherever it was believed that the deity not merely responded to prayer, but gave direct answers by omen or by oracle to inquirers, the frequentation of the prophetic seat would naturally increase. Further, as the political strength of any tribe grew, that would be attributed in a multitude of cases to the superior power of its tutelary god, or, where they worshipped the same deity as their neighbours, to some more acceptable mode of paying that worship, whence the custom would grow of making the principal temple of the most powerful tribe the meeting-place of the confederacy, as well for political deliberation as for the more directly religious purpose of reaffirming the common pact with sacrificial ceremonies. And if the strongest tribe passed from the stage of hegemony to that of sovereignty, whether by cession or by conquest, so becoming the nucleus of a nation or kingdom, the same feelings would operate yet more powerfully,—the subject tribes being either compelled to accept the gods of their conquerors, or voluntarily adopting them from a conviction of their superior might. Certain temples would in this wise become national from having been tribal, and in large empires, such as Egypt and Assyria, would collect worshippers from all the various peoples ruled under a common sceptre. The second stage in the genesis of special sanctuaries is peculiar to religions with a real or supposed historical basis, and takes the form of devotion towards localities which have been the scenes of important events in the lives of personages revered in the creeds of those religions. And the third stage, belonging to a much later period than either of the former, when self-consciousness had become more developed, is that where the aim of the pilgrims is primarily subjective, to stir up certain emotions in their own minds, through the means of the associations connected with special localities. But in each and all of these the fundamental underlying thought is the same, the localization of deity, the almost insuperable difficulty which the ideas of omniscience and omnipresence offer to undeveloped intellects.

It will be convenient, in tracing the history of pilgrimages, to begin with those which belong to the various forms of heathenism, ancient and modern, as pertaining, whatever be their actual date, to an earlier stage of mental evolution than the Jewish, Christian, and Mohammedan ones.

The first pilgrimages, then, of which we have any trustworthy knowledge, are those of ancient Egypt. The mythology of the Egyptians is even yet but imperfectly understood, but it is at any rate clear that, just as the votaries of Vishnu and of Siva keep apart in modern Hindustan, so the chief deities of the Egyptian pantheon had cults which were as often rival as complementary, and that the emulation of the competing temples took the form of bidding against each other for popular favour by the splendour of their chief yearly festivals. We are obliged to have recourse to Herodotus and Plutarch for information as to the general cycle of feasts nationally observed; for, although local calendars and rubrics of festivals have been discovered in several places, nothing cognate with Ovid's *Fasti* has yet been found in Egypt. Herodotus notices that, instead of having but one yearly national festival (*πανήγυρις*), the Egyptians had six, the principal of which was that of Artemis (i.e., Bast or Sekhet) at Bubastis, to which the pilgrims went in boats crowded with both sexes, playing on castanets and flutes, and singing to this accompaniment. They landed at every town along the

river to perform orgie dances, and at Bubastis itself offered great sacrifices, besides feasting copiously, in particular consuming vast quantities of grape-wine. He states the numbers assembling on this occasion, exclusive of children, to average 700,000. Next to this ranked the festival of Isis at Busiris, attended with ceremonies of mourning, most probably in memory of the sufferings of Osiris. Third in order was the feast of Athene (Neith) at Sais, celebrated at night, with illuminations. Fourth was the festival of the Sun (Ra) at On or Heliopolis; fifth that at Buto in honour of Latona (Buto or Uat). These two were attended with simply sacrificial rites, and there were no symbolical ceremonies in addition. Last came the festival of Ares (Har-tash, the Hertosi of Cedrenus) at Papremis, at which there was a rough tussle, symbolizing war, between the temple-attendants and the pilgrims, in which lives were sometimes lost. There was another high festival, that of Apis at Memphis, not included by Herodotus in his list, perhaps because not of yearly recurrence, besides the much frequented oracle of Ammon at Thebes, whither it had been transferred from Meroe, its first seat in Egypt. And it is noticeable that there was no pilgrimage at all to the most sacred spot in Egypt, the island of Philæ, the burial-place of Osiris, because its very sanctity made it "tabu" to lay folk. The mysteries, in like manner, being rigidly confined to a few, did not form an occasion of pilgrimage.

Assyrian and Babylonian. As regards the great Mesopotamian empires, our knowledge does not yet enable us to say that pilgrimages entered into their religious system, though we may not unreasonably infer so from the size and wealth of several temples, notably those of Ishtar, from the Assyrian custom of imposing their own deities upon conquered nations, and from the example of one great religious assembly from all the provinces of the Babylonian empire, recorded in Daniel iii. There may, perhaps, be indirect proof of Babylonian pilgrimages in what Cyrus states in his cylinder-inscription, namely, that Nabonidus had offended the gods by transporting their images to Babylon, and thus, as it were, making them perform pilgrimage.

Persian. The ancient Zend creed of the Medes and Persians, having no temples for worship, had no pilgrimages; but in its later Mithraic form, the initiation of neophytes by the Magians into the mysteries, through a painful course of purification (curiously resembling one prevalent in Ireland far within the present century), in a cavern or grotto at Babylon, necessitated a pilgrimage thither on the part of those who desired to become experts; and Lucian has left some account of its rules in his *Menippus*.¹

Phœnician. Amongst the Phœnicians there are clear traces of at least two great pilgrimages in honour of Ashtoreth, one to Aphaca (probably the Aphek of Scripture), celebrated for a yearly miracle of a ball of fire appearing on the mountain summit, and thence falling into the sea. The obscene rites for which this temple was infamous led to its destruction by Constantine the Great (Euseb., *Vit. Const.*, iii. 56). **Syrian.** The other great Ashtoreth pilgrimage was to Hierapolis in Syria, frequented by votaries from all the Semitic races except the Jews. Antioch was also a great centre of this cult, as also of that of Thammuz, but, strictly speaking, there is no proof of a Thammuz pilgrimage, nor of one in honour of Melkarth, though his worship was carried from Tyre, its chief seat, into all the Phœnician colonies, and the famous oracle of his temple at Gades drew crowds of inquirers annually. In Palestine proper, though the cults of Baal, Ashtoreth, Moloch, Dagon, and Beelzebub were widespread and persistent, and though the name Jericho

probably, and Ashtarothe-Karnaim certainly, point to a seat of moon-worship, as Bethshemesh does to one of sun-worship, there is no direct evidence of organized pilgrimages to these places.

In ancient Hellas there were four classes of religious Greek observance more or less cognate with pilgrimage, though not in any case identical therewith. First may be placed the consultation of oracles,—those of Apollo at Delphi, of Zeus at Dodona, of Trophonius at Lebadeia, and of Asclepius at Epidaurus (the last of which was resorted to also for the cure of disease) being the most famous and most frequented, while, outside Greece and its colonies, the oracle of the Libyan Ammon in the desert south of Cyrene was also in much esteem. Next come the four great national festivals and games, the Olympic, Pythian, Nemean, and Isthmian, attended by crowds from all Greek states, not only as attractive shows, but as religious ceremonies.² Thirdly may be named the more local or tribal festivals, such as the Panathenæa, the feast of the Charites at Orchomenus, that of Hera at Samos, of Aphrodite at Paphos, and of Artemis at Ephesus, which drew together many worshippers besides those who were specially bound to visit the shrines in question. But the closest parallel to the Christian theory of pilgrimage is found in the celebration of the Eleusinian mysteries (see MYSTERIES), the special likeness of which to pilgrimages of a later day lies in the notion of merit and spiritual benefit attached to initiation, to the belief that happiness in a future state of existence would be promoted, nay, insured, by admission to the ranks of the mystæ.

The Latin customs bear a certain superficial likeness to Roman. the Greek, in that local oracles, such as those of Faunus, of Albunea, of Fortuna, and of the Sibyls, were much frequented; there are traces of great tribal sanctuaries and gatherings, such as the worship of Jupiter Latialis on the Alban Mount, of more narrowly restricted tribal cults, such as the Julian worship of Vejovis at Bovillæ and the Fabian sacrifice to Hercules on the Quirinal, and of at least two temples to which regular pilgrimages seem to have been made—those of Juno Sospita at Lanuvium, and of Vesta (perhaps of all the Penates also) at Lavinium. But, apart from racial and theosophic differences of belief, there was one factor at work in Italy which tended to bring about a wholly different character of popular religion from that which was evolved in Hellas—the overmastering centralization of Rome, and the practical identification of all solemn worship (apart from the rustic ceremonies in honour of minor and little-known deities) with the apotheosis of the Republic. Hence, after the chief seat of Roman worship was transferred from the Regia to the Capitol, pilgrimage proper disappeared, for the local gods of each newly absorbed city or state were added to the original triad of Roman gods, and to the other Sabine triad, moved from the Quirinal to the new sanctuary, and it becomes impossible to distinguish clearly between the purely political ceremonies performed in honour of gods viewed primarily as the tutelars of Rome and voluntary resort to the great temple for the personal cult of any particular deity enshrined there. One relic of the older custom seems to have survived till later times, namely, the pilgrimage of Roman women barefoot to the temple of Vesta in the Forum on June 9 every year.

No pilgrimages seem to have been usual in the Teutonic Teutonic and Slavonic religions, though both had special temples and regarded as more sacred than the remainder, and in the Slavonic case of the latter we know with tolerable accuracy that Kieff, Novgorod, Rethra in Mecklenburg, Karenz, Winneta

¹ This is probably the source of the Moslem legend of Harût and Marût, the fallen angels chained in a cavern at Babylon, who will teach magic to such as consult them in a prescribed manner.

² The Panhellenic festival at Ægina is omitted, as a mere factitious device of the emperor Hadrian, when classical paganism was dying, and not a real Greek custom.

and Julin (isle of Wollin), Stettin, and lastly Arkona in the isle of Rügen, succeeded one another as the chief seat of the worship of Perun, Lada, Bielbog, and other principal Slavic deities, and were necessarily attended by much larger bodies of worshippers than temples of less account, more thinly officered, and inferior in repute for the learning and prophetic powers of their priests.

Mexican. Directing our attention to an entirely different region of the world, we learn that in 1519, when Cortes entered Cholula in Mexico, he found it a great resort of pilgrims to the huge temple of Quetzalcoatl, then of unknown antiquity, as founded by a race earlier than the Aztecs, and built upon a colossal mound, vying in dimensions with the largest pyramids of Egypt. And what is yet more curious, besides this principal shrine, there were subsidiary tribal temples in the city, restricted to the uses of the several allied or kindred nations, who desired to have their own sanctuary in the holy city, precisely as churches of different nationalities are found in Jerusalem and in Rome to-day. And similarly in Peru, the great Temple of the Sun at Cuzco, with its encircling girdle of chapels dedicated to minor deities, was visited by pilgrims from all parts of the empire; nay, it was even regarded as a misfortune to fail in accomplishing the journey.

Indian. India, however, is above all others the land of pilgrimages, for it has observed them during a longer unbroken period than any other country of which we possess sufficient records, and for frequency and multitude it would be difficult to find any parallel. The most celebrated of them are those to the temple of Jagan-nâth at Puri in Orissa, Benares, Hurdwar, Ganga-Sagara, Gangotri, Jumnotri, Prayâga (Allahabad), Râmêswara, Gaya in Behar, and Ayodhya or Oudh. Apart from the motives, common to all pilgrims, of acquiring religious merit or expiating sins, these Indian shrines are frequented for the performance of *śraddha* ceremonies in honour of deceased ancestors or as votive acts for the recovery of the sick, or, again, to carry the ashes of deceased kindred to be scattered in the waters of some sacred or purifying river. Every great river in India, with some lakes, tanks, and springs, is regarded as permeated with the divine essence, and as capable of cleansing from all sin. Hence the favourite resorts are river sources and confluences, while Benares, as situated on the Ganges itself, is the holiest spot in Hindustan. The other most frequented shrines are usually associated with the cults of Krishna, Siva, and Râma. All these are exclusively connected with Brahman rites, for the entire extirpation of Buddhism from the Hindu peninsula has prevented any special sacredness from continuing to attach to the scenes of Gautama Buddha's life (though the Buddhists allege that the sanctity of Benares is due to its having been the residence of Buddha himself and the scene of his earliest preachings); and it is in Ceylon only that two Indo-Buddhist pilgrimages survive,—that of Adam's Peak, and the yet more popular one to the temple of Kandy, where the *Dalada Malagawa*, or tooth of Buddha, is an object of special veneration. For northern Buddhism the chief shrines are Lhassa in Tibet, the seat of the Dalai Lama, and Urga in northern Mongolia, the seat of the Tesho-Lama, Krashis Lunpo in Further Tib the seat of the Pantshen Lama. Before the Brahman revolution, which drove Buddhism out of India, pilgrimages to the chief scenes of Gautama Buddha's life were common; and notably Kapilavastu, his birthplace, Benares, where he began his mission, and Kasinagara, where he died, were much frequented, especially by Chinese converts. The narratives of some of these, Fa Hian, Hwai-Seng, and Sung-yun, and Hwen-T'sang, the most noteworthy of them all (see vol. xii. p. 418), who came to visit the holy places and to collect the sacred books, are still extant.

In China pilgrimages are made to several of the more Chinese sacred spots both by Buddhists and Confucianists. Wutai-shan in Shan-si is the chief resort of Buddhist pilgrims, and Tai-shan, the mountain sacred to Confucius, that of Confucianists (Williamson, *Journeys in North China*). In Japan both the older Shintô nature-worship and the newer ^{Japanese} Buddhist creed have their several sanctuaries and pilgrimages. The principal Shintô pilgrimages are those to Isé in the department of Watarai, and to the sacred mountain Fuji. There are two temples at Isé, ranking in sanctity first of all Shintô shrines, and the special seat of the worship of Ten-shôkô-daigin, the Sun-Goddess, from whom the Mikado is held to descend. Two great festivals are held yearly at Isé, in the sixth and twelfth months, and are known as *O-barai no matsuri*, "great purification feast," being held to effect the purifying of the whole nation from the sins of the previous half year. Tickets inscribed with the names of the gods of Isé, and especially that of the Sun-Goddess, are issued at the temples and their agencies (being formerly sold by hawkers corresponding to the pardoners of mediæval Europe), and are carefully preserved in the domestic shrine of Japanese houses, being supposed to avert all peril for six months, but requiring renewal at the end of that period. The pilgrims to Isé number many thousands yearly, and are known as they return by bundles of charms wrapped in oiled paper, and hanging from the neck by a string. The pilgrimage to Fuji takes place in summer, and the pilgrims go clad in white, and carrying bells. They ascend the mountain so as to reach the summit before sunrise, when they turn to the east, clap their hands, and chant a hymn to the Sun-Goddess. There are also many local Shintô pilgrimages of less note. Buddhism in Japan is broken up into several sects, having each of them their own pilgrimages; but the most frequented are those of the god Fudo at Narita and the sacred mountain of Oyama, each some 30 miles distant from Tokio. These both belong to the Shingou sect, the earliest introduced into Japan. The Hokke or Nichiren sect make pilgrimages to the monastery of Ikegami near Tokio, and to that at Mount Minobu, about 100 miles to the west, between which two shrines the relics of the founder are divided. Ninety miles north of Tokio are the shrines of Mount Nikko, also a great Buddhist pilgrimage, where the shoguns are buried, and where the founder of the Tokugawa dynasty is worshipped under the name of Gongen.

So much will suffice to have said concerning the various heathen pilgrimages, and we may now consider those of the Hebrew religion and its two derivatives, Islam and Christianity.

The legislation of the Pentateuch is precise in making Jewish resort to one central shrine a positive and fundamental precept, binding on the whole nation, obviously with the double object of cementing national unity and of guarding against the erection of local sanctuaries, which were liable to be diverted to idolatrous cults (see PENTATEUCH). Under the judges and the kings we find many traces of pilgrimage, not only to the sanctuary of the ark at Shiloh, and afterwards to Jerusalem, but to local high places, such as Ophrah, Mizpah, Dan, Bethel, and Beersheba. In truth, it is not till the post-exilic period that the supremacy of one national sanctuary is assured (though a pilgrimage even after the destruction of the temple is recorded in Jeremiah xli. 5, showing that the mere site was held sacred), for the local devotion of the high places resisted all the efforts of the reforming party under Hezekiah and Josiah even in the kingdom of Judah itself. Since the final overthrow of the Jewish polity by Titus and Hadrian, no effort has been made either to establish a centre of sacrificial worship anywhere outside Palestine (as in the

curious episode of the temple of Heliopolis in Egypt), or to revive it in Jerusalem itself, where, even now, the synagogues and colleges of the Sephardim and Ashkenazim are entirely separate and independent organizations, and show no tendency to coalesce into the nucleus of a national system. Hence, as the political and religious motives for the pilgrimage to Jerusalem have both dropped into abeyance, the custom itself is no longer regarded as binding, and, though it is not obsolete, inasmuch as a visit to the Holy City is considered a meritorious act, yet it has now, like the pilgrimage to Hebron, more of an emotional and historical character than a ceremonial one, so that it is not in the strict sense a pilgrimage any longer.

Although the Mohammedan pilgrimages are much later in chronological order than the Christian ones, it will be more convenient to consider them briefly first. They consist, then, of two main classes, which may be distinguished conveniently by Latin theological terms, as those of "obligation" and those of "devotion." There is properly only one Moslem pilgrimage of obligation, that to Mecca, which still often draws an annual contingent of from 70,000 to 80,000 pilgrims (see MECCA). It is in truth a pagan survival which proved too powerful for extirpation by Mohammed. The Kaaba had been constituted the national sanctuary of Arabia about 100 B.C., and contained, besides the famous Black Stone, some three hundred and sixty idols of various Bedouin tribes, united in one pantheon, exactly as with the Capitol of Rome; and, though it was possible to sweep the idols out of the Kaaba, it was not so easy to deconsecrate the spot, but far more convenient to give it a new sanction.

The Mohammedan pilgrimages of devotion are very numerous, and are chiefly connected with the saint-worship which has overlaid and obscured the original strict monotheism of Islam. Chief amongst the sacred shrines of this second class stands the tomb of Mohammed at MEDINA (*q. v.*), but, holy as it is considered, and meritorious as a visit to it is accounted, it is in no sense binding on a Moslem's conscience, and only about one-third of the Meccan pilgrims proceed thither. Other sanctuaries abound in all Mohammedan countries, of which a few, like Abraham's tomb at Hebron, are honoured by all Mohammedan sects, while others are peculiar to the Sunnites and Shiites respectively, and others again, such as Kairwân in Tunis, and Wazan in Morocco, and still more the tombs and oratories of merely local saints or *welis*, found in almost every Moslem town or village, are restricted to a comparatively small body of votaries. The most famous, after the Pan-Islamic pilgrimages, are the great Shiite sanctuaries, of which there are three:—Meshed in Khorâsân, with the tomb and mosque of Imam Riza, said to attract almost as many yearly pilgrims as Mecca itself; Khoum in Irak Ajemi, where Fatima, wife of Imam Riza, is buried; and, yet more sacred than either, Kerbela in Mesopotamia, in the Turkish dominions, about 28 miles north-west of the ruins of Babylon, where is the tomb and mosque of Imam Hosein, grandson of Mohammed (see KERBELA and MOHAMMEDANISM). There is a passion-play performed there at the yearly commemoration, which draws enormous crowds from all parts of Persia and other Shiite regions, and the title *hâjj* attaches to all who make the journey. Some idea of the multiplicity of minor pilgrimages amongst Moslems may be gathered from the fact that in the city of Damascus alone there are one hundred and ninety-four places of resort by pilgrims, and fourteen more in the environs. A great reaction against the whole system, inclusive of the invocation of saints, took place under the Wahhabis in the last century, in the course of which countless *welis* or tombs of Moslem saints were destroyed, including even those of Hosein and

Mohammed himself; but, on the overthrow of the fanatics by Mohammed Ali, the customary practices were restored, and have continued in full vigour ever since.

Christian pilgrimages were at first limited to Jerusalem and its immediate neighbourhood, including Bethlehem. It is probable enough that the local church of Jerusalem regarded the various scenes of the gospel history, and notably of the Passion and Resurrection, with special reverence, and would guide the steps of visitors to the most sacred localities while the city yet stood, and point out the sites, as nearly as possible, after the work of Titus had been completed by Hadrian, and a vast mound of earth, on whose summit rose a temple of Venus, had been raised over the Holy Sepulchre. But this is matter of conjecture rather than of knowledge. There is no actual proof of very early Christian pilgrimage to the holy places, though the belief was already current at the close of the 4th century that the custom had prevailed unbroken from apostolic times, as is distinctly asserted by Paula and Eustochium in their letter to Marcella (*Epist. Hieronym.*, xvii.), written in 386, wherein they state also that of which they are more trustworthy witnesses, that pilgrims then flocked from Armenia, Persia, India, Ethiopia, and even Gaul and Britain, to visit the cradle of Christianity. But in point of fact the earliest pilgrim of whose visit as a religious act we have definite proof is Alexander, a Cappadocian bishop, who came to Jerusalem in consequence of a dream (212), and was elected coadjutor to Narcissus, then bishop of the diocese (Euseb., *E. H.*, vi. 11). Origen, who was a friend of Alexander, is another early example, but his own words (*Comm. in Evang. Joann.*, vi. § 24) imply that he came rather in the modern spirit of devout scholarly inquiry than as a pilgrim in the strict sense. He paid a short visit in 216, and returned in 231, to settle down for a time at Cæsarea, where he opened a school of theology in 238. It is not till after the pilgrimage of the empress Helena (the first quite unquestionable event of the kind) about 326 or 328, that the fashion set in, accompanied with the desire to bring back some relic, either inherently sacred or at least hallowed by contact with certain venerated spots. That the temper of the time was not a very critical one is sufficiently proved by the casual mention by St Chrysostom of a pilgrimage as commonly practised to Arabia in order to see the dunghill on which Job sat, and that by visitors from the very ends of the earth (*Hom. v. de Statuis*).

But another kind of pilgrimage, destined to be more powerful than that to Jerusalem, began to be popular nearly at the same time, that to the tombs of distinguished martyrs or confessors. In the present day, the passionate admiration of the Christians of the 3d, 4th, and 5th centuries for the martyrs as a class seems somewhat disproportioned to the part they actually played in the history of Christianity, which was more effectually propagated and maintained by the eminent teachers and divines of the ancient church. But the truth is that they supplied just the element of enthusiasm which was needed to sustain the courage and endurance of the humbler Christian laity under the stress of recurrent persecutions; and, when peace was finally secured under Constantine the Great, there were so many families which counted one or more martyrs amongst their kindred, and viewed such kinship as a patent of nobility, that everything favoured the rapid development of pilgrimages to places in which so many had a direct personal, as well as a corporate religious, interest. So much did the notion begin to prevail that pilgrimage was almost a necessity of religion, and that prayer could be heard more assuredly in particular places, that warnings against error of the kind were uttered by

teachers whose own acts had helped to propagate the opinion in question. Thus, only a few years after the letter above cited, urging Marcella to migrate to Bethlehem, St Jerome writes to Paulinus (393) pointing out that many of the most celebrated saints and ascetics had never visited the holy places, that heaven is just as open from Britain as from Jerusalem, and that the circumstances of life in Jerusalem itself were far from helpful to devotion. But his own abode at Bethlehem, the celebrity of the religious houses he founded and directed there, and the unlike tenor of other letters he wrote, entirely counteracted this advice. St Chrysostom at one time speaks of the needlessness of pilgrimage (*Hom. i. in Philem.*; *Hom. iii. and iv. ad pop. Antioch.*), and at another expresses his own wish to see the relics of St Paul at Rome (*Hom. xxxii. in Rom. ii., iii.*; *Hom. viii. in Eph. ii.*). So, too, St Augustine contributed powerfully to promote pilgrimages to the shrines of saints, by sending in 404 two clerical disputants to the shrine of St Felix of Nola, in the hope that some miracle would be worked there to decide the matter, though no such signs had been granted at the grave of any African saint (*Ep. lxxviii.*). And in another place he attests the working of many miracles by the relics of the protomartyr St Stephen in various African towns where portions of them had been shrined (*De Civ. Dei*, xxii. 8). Nevertheless, in yet a third place he appears to condemn this very temper as mere superstition, stating that, while he knows many professing Christians who are worshippers of tombs and pictures, "the church condemns them, and daily strives to correct them as evil children" (*De Mor. Eccl. Cath.*, xxxiv. 75, 76).

Here, too, example proved stronger than precept, and the only unqualified opposition to the popular tendency which issued from any quite unimpeachable source (for Vigilantius and Jovinian cannot be fairly cited) is the remarkable letter of St Gregory of Nyssa to a friend, on the subject of pilgrimages to Jerusalem, the heads of which are as under:—there is no divine precept for the usage; the moral dangers of the journey, from bad companions and from the quality of the inns, are great, especially to women, and above all to nuns; the immorality and irreligion of Jerusalem itself are gross and notorious. True, he had gone thither himself, but it was on public ecclesiastical business, connected with the Arabian Church, and he had travelled in a public vehicle with a company of monks. He did not find his faith stimulated or improved in any way by a sight of the scenes of the gospel history, and he recommends others to stay at home, assuring them that no spiritual benefit is lost by so doing, and no spiritual gain acquired by visiting the most sacred places without inward amendment (*Epist. ii.*). The authenticity of this epistle has been challenged, but on no sufficient grounds.

What makes the devotion to the tombs of saints such a powerful factor in ecclesiastical history is that, after the Holy Sepulchre itself, no grave had such a hold on Christian imagination as that where the bodies of the two chief apostles, St Peter and St Paul, were held to rest in Rome. And consequently, as the division of the empire lessened the intercourse between East and West, as the decay of the old lines of communication made travelling more difficult, and as the advance of Mohammedanism in Syria and Palestine made it more dangerous also in that direction, Rome gradually supplanted Jerusalem to a great degree in the West as the goal of pilgrimage, and the enthusiasm of the visitors did much to consolidate the papal monarchy over Latin Christendom. So markedly did this new influence prevail that it has left its trace in more than one European language. The Low Latin *romerius*, *romipeta* for a pilgrim anywhither, *romeria*, *romi-*

petagium for the actual pilgrimage, the obsolete French *romieu*, *romipète*, *romivage*, the still current Spanish *romero*, *romeria*, and Portuguese *romeiro*, *romaria*, the Italian forename *Romeo*, and the English *romare* (*Piers Plowman*) attest the celebrity and popularity of this pilgrimage, into which soon entered such further ideas as the desirability of confessing sins to the pope personally and obtaining absolution from him, the reference of private cases to papal arbitration on the part of bishops and other ecclesiastical judges, and the injunction of the journey as in itself a penance, a notion prevalent in the Gallic churches as early as the close of the 5th century (*Cæsar. Arelat.*, *Hom. iii.*). Nowhere was the pilgrimage to Rome more popular than in Saxon England, and amongst the crowds of penitents who made the journey were four kings, Ceadwalla, Ine, Coinred, and Offa, all of whom died in Rome, two of them as monks (Beda, *H.E.*, v. 7, 19). There were not wanting efforts to check the movement. Apart from the theological objections raised by Claudius of Turin, there is a letter extant from Boniface of Mainz, an Englishman born, to Cuthbert, archbishop of Canterbury, written about 743, begging him to get a canon enacted to forbid the pilgrimage to Rome, especially to nuns, on the ground of the moral perils of the road, stating that no city of France, Lombardy, or Italy was without Englishwomen leading depraved lives, whose virtue had fallen during pilgrimage. And the council of Chalons, in 813, enacted a canon to check pilgrimages both to Rome and to the shrine of St Martin at Tours (then the most famous sanctuary in France), on the ground of serious abuses on the part of both clergy and laity; and the council of Seligenstadt made a like effort in 1022. But even the robber barons who looked on pilgrims as their natural prey could not arrest the movement (which was specially stimulated, as we learn from Radulphus Glaber, in 999 and 1000 by the belief that the end of the world was at hand), and the Roman pilgrimage reached its height in the Middle Ages through the institution of the Jubilee, or plenary indulgence to pilgrims, by Boniface VIII. in 1300, when 200,000 are said to have availed themselves of it, and smaller but still considerable numbers on its various repetitions at irregular intervals since. The pilgrimage to Jerusalem received fresh stimulus in the 9th century by the first occurrence of the alleged miracle of the heavenly fire on Easter Eve at the Holy Sepulchre, and continued to be frequented till checked by the fanaticism of the caliph Hakem-Biamr'illah about 1018, and more severely and permanently by the Seljukian Turks on their conquest of Syria, which occasioned those armed pilgrimages, the crusades, to whose history this branch of the subject thenceforward belongs. Meanwhile, a third class of sanctuaries had been steadily coming into notice and popularity, consisting neither of the seats of great historical events nor of the ascertained resting-places of eminent saints. These were the purely legendary shrines, the sites of some alleged vision, of the supernatural discovery of hidden relics, or of the presence of a wonder-working image or picture. One of the earliest and most famous of these was that of Compostella, where the relics of St James the Great were said to be discovered in 816, and, after being again hidden for many centuries, to have been discovered afresh in 1884. This was one of those most frequented by English pilgrims, no fewer than 2460 licences being granted for the journey in the one year 1434 (Rymer, *Fœd.*, xi.).¹

¹ This concourse of English pilgrims was soon looked on in France as politically dangerous, so that in the 14th century, when Pedro the Cruel was dethroned by Henry of Trastámara, the latter was compelled by his allies to refuse entrance into Spain to all pilgrims who had not licence of transit from the king of France. This kind of jealousy

Another, which became the Bethlehem of the West, as Rome had become its Jerusalem, was Loreto, where, ever since 1295, the Santa Casa, declared to be the home of the Holy Family, miraculously transported from Nazareth, has been frequented by pilgrims till very recent times, when its popularity has waned. Other famous shrines, some few of which even still attract yearly crowds of pilgrims, are Einsiedeln in Switzerland; Assisi, Oropa, Varese and Vicovaro in Italy; Monserrat and Guadalupe in Spain; Mariazell in Austria; Oetting and Eberhardsclausen in Germany; Walsingham, Becket's shrine at Canterbury, Peterborough, St Davids, and Holywell in England and Wales; St Andrews in Scotland; Chartres, Notre Dame de Liesse, Notre Dame de Rocamadour, and Notre Dame des Victoires, with Ste Anne d'Auray in Brittany, in France; and Hal in Belgium. Devotion to these shrines was encouraged and developed by copious indulgences annexed to them; but this system in the long run became adverse to pilgrimages, because exactly the same privileges were annexed at a later time to acts much more easy of performance. Thus, the wearers of the cord of St Francis, every time of reciting certain brief prayers, acquire all the indulgences attached to the holy places of Palestine, Rome, Assisi, and so forth, and have naturally little inducement to perform toilsome and costly journeys thither.

There is a further small class of pilgrimages, differing from all others in being neither permanent nor yearly, but periodical at various long intervals. They are usually connected with the exposition of the principal relic or relics in some important church, an event which rarely occurs. Such are the pilgrimages of Cologne, to the shrine of the Three Kings, and that of Treves, where the alleged seamless coat of Christ has been displayed for popular devotion, and has been visited by vast crowds of pilgrims.

Pilgrims in the Middle Ages were known by a peculiar garb and various badges, the hood and cape, the staff and scrip and water-bottle, and the low-crowned hat, turned up in front, and fastened with strings, being common to all, while the palm specially marked a pilgrim from the Holy Land; a shell, one from Compostella; a bottle or bell, one from Canterbury, and so forth. They had many privileges and advantages. They were exempt from toll, their persons were inviolable, and any injury done to them incurred the penalty of excommunication; they were entitled to shelter, fire, and water in all convents on their road, and the needier ones to food in addition; and there were resting-stations erected for them on all the great lines of travel, sustained sometimes by voluntary offerings, and sometimes by public imposts; while in Rome, above all, institutions for their reception and relief were established early, and are still in active operation.¹ Nevertheless they declined in repute, not only by reason of the feigned devotees who joined them for purposes of vagrancy and mendicancy, and even from worse motives, but because many notorious criminals were customarily sent on pilgrimage as a punishment, with no care to isolate them from their innocent companions. The general charge of moral deterioration as a result of pilgrimage, which recurs from the fourth century onwards, is specifically brought by Langland in respect of truthfulness:—

"Pilgrims and palmeres plighthen hem togidere,
For to seken seint Jame and seintes at Rome.
They wenten forth in hire wey, with many wise tales,
And hadden leve to lyen all hire lif after."

—(*Vision of Piers Plowman*, pass. i. line 82).

lasted very long, for there are edicts of Louis XIV. and XV. forbidding foreign pilgrimage to French subjects without the written permission of their bishop, and the counter-signature of a state official, under pain of the galleys for life. They bear date 1671, 1686, and 1738.

¹ For more details see Mr Scudamore's articles, "Holy Places" and "Pilgrimages," in Smith's *Dictionary of Christian Antiquities*.

Hence pilgrimages were attacked with the weapons of ridicule, and the most celebrated satires upon them are the chapter in *Reineke Fuchs*, describing Reynard's adventures as a pilgrim, and the yet wittier squib of Erasmus, *Peregrinatio religionis ergo*, in which he gives a sarcastic account of the pilgrimage to Walsingham, which had much to do with destroying the prestige of not only that particular one, but most others also. The French Revolution all but completed the work of the Reformation in causing pilgrimages to decline seriously, where they were not entirely abolished, in the West, though they were still able to maintain their ground in retired and unchanging places such as Brittany, various places in central Italy, and in Ireland, where the severely penitential pilgrimages of Lough Finn, Lough Dearg, and Croagh Patrick are not yet obsolete. There was a remarkable recrudescence of the spirit of pilgrimage under the pontificate of Pius IX., notably to the new sanctuaries of La Salette and Lourdes in France, which reached its height about 1872-73, but has shown signs of subsiding again since.

In the Eastern Church, pilgrimages have not for many centuries formed so important a part of popular religion as in Latin Christendom, and the number of frequented shrines is very small. In the Greek Church properly so called, Mount Athos, with its numerous monasteries, where the great yearly gathering is on the feast of the Transfiguration, ranks next to the visit to the Jordan (Tozer, *Highlands of Turkey*, i. 103). After Mount Athos comes a shrine in the island of Tenos, where, in the cathedral church of the Panagia Evangelistria, is preserved an icon of the Madonna, alleged to be wonder-working, and said to have been discovered by means of a dream in 1824; the annual concourse of pilgrims twice a year, on the feasts of the Annunciation and the Assumption, is very great. Three alleged pictures of the Blessed Virgin by St Luke—at Megaspelion, at Sumelas in the mountains behind Trebizond, and at Stiri in Mount Helicon—are also much visited. Etchmiadzin is the chief Armenian pilgrimage, besides which are those of Kaisariyeh and Mush (Tozer, *Turkish Armenia*, pp. 161, 271). And finally, the chief Russian pilgrimages are to the Petcherskoilavra at Kieff (said to be visited by 200,000 pilgrims yearly), the Solovetsk monastery near Archangel, and the Troitsa, close to Moscow, besides many more locally popular shrines. (R. F. L.)

PILLORY. This was a mode of punishment by public exposure of the offender on a platform or scaffold long used in most countries of Europe, originating probably with the Anglo-Saxons, one of whose methods of punishment as described by Strutt is nearly identical with the instrument which eventually became known as the pillory. The etymology is not quite clearly made out. It is most probably connected with *pillar*, Fr. *pilier*, M. H. German *Pfälaere*, but there are forms with an initial *s* (Prov. *espilori*, Low Lat. *spilorium*) which this derivation does not explain. The more usual French term is not *pilori* but *le carcan*. The Germans have *Preller*. *Healsfang* or *halsfang* (Anglo-Saxon for a catching of the neck) was the old English name. The word was also sometimes applied to the pecuniary mulct paid in commutation of the punishment. No punishment has been inflicted in so many different ways as that of the pillory. Sometimes the machine was constructed so that several criminals might be pilloried at the same time, but it was commonly capable of holding only one. Douce (*Illustrations of Shakespeare*) gives six representations of distinct varieties of this instrument. In Griffiths (*Chron. of Newgate*) and in a learned and exhaustive account of the pillory by Jewitt (*Reliquary*, April 1861), examples will also be found, and notably of the pillory for women, which differed in form from that in use for male offenders. It would

appear that it had not always been customary to subject women to this form of punishment; for them the thew or the tumbrel, which latter was probably the same as the ducking or cucking stool often spoken of in the early English laws in conjunction with the pillory, was reserved. These varieties are all reducible, however, to the simplest form of the pillory as ordinarily known, which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame so as to be exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle or carcan (hence the French name), which secured the heads and hands of several persons at the same time.

In the statutes of Edward I. it is enacted that every pillory or stretch-neck should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. Some of the offences punished in England by the pillory will be found enumerated in the statute 51 Hen. III. c. 6 (1266), comprehending chiefly indictable offences not amounting to felony (commonly called misdemeanours), such as forestalling and regrating, using deceitful weights and measures, perjury or subornation of perjury, libel, seditious writings, &c. Later on, the punishment of the pillory was ordained for courtesans, common scolds, and brawlers and other like delinquents both male and female, and in the later years of its existence, notably during the 17th and 18th centuries, it was much resorted to as a punishment for political offenders, who on some occasions experienced the roughest treatment at the hands of the mob, ill-usage resulting in some instances on record even in death. The intention of setting a criminal in the pillory was that he should become infamous and known as such afterwards by the spectators. Examples have not been wanting, however, in which much sympathy has been both felt and expressed by the populace for the individual subjected to this punishment. The duration of the punishment was usually assigned at the discretion of the judge who passed the sentence, though sometimes it was fixed by law. The form of the judgment was that the defendant should "be set *in* and *upon* the pillory"; he was consequently said to stand *in* the pillory, not *at* it.

The pillory was abolished in Britain, so far as related to all offences save perjury and subornation, in 1816 (56 Geo. III. c. 138), and finally altogether by statute 7 Will. IV. and 1 Vict. c. 23 in 1837. In the former Act power had been reserved to the court to pass sentence of fine or imprisonment or both in lieu of the pillory. The punishment was done away with in France in 1832 upon the revision of the penal code, and has now indeed been withdrawn from most of the modern systems of penal law.

PILOT. The English Merchant Shipping Act of 1854 (17 & 18 Vict. c. 104) defines a pilot as being a person duly licensed by any pilotage authority to conduct ships to which he does not belong as one of the crew. Pilots are in fact taken on board to superintend the steering of the vessel, where the navigation is difficult and dangerous, in consequence of their special knowledge of particular waters; and it is to this class alone that the term now applies, whereas in early times the pilot was the steersman, or the individual who conducted the navigation of a ship across the ocean and out of sight of land. The word seems to be of Dutch origin, and to mean primarily a person who conducts a ship by the sounding line (*peillood*). Cowell (*Law Dict.*), describing *lodemanage*, speaks of it as

the hire of a pilot for conducting a vessel from one place to another,—a *lodesman* (Ang. Sax. *lād-man*, a leader) being a pilot for harbour and river duty. During the period of his charge the whole responsibility of the safe conduct of the vessel devolves upon the pilot. Most systems of maritime law have made the employment of pilots compulsory, though this does not usually apply to ships of war. One effect of neglect or refusal on the part of the master of a ship to take a pilot is to discharge the insurers from their liability.¹ Excepting under extraordinary circumstances (such as where it is evident that he is acting rashly or is intoxicated, or is palpably incompetent) a master would not be justified in interfering with the pilot in his proper vocation. In England, societies or corporations have long been established for the appointment and control of pilots in particular localities; and of these the Trinity House, London, owing to the number of the pilots under its control, and the large extent of its jurisdiction, may be deemed the principal. The laws relating to pilotage were consolidated by 48 Geo. III. c. 104 (1808), which was amended by 6 Geo. IV. c. 125 (1825); further regulations were made by 16 & 17 Vict. c. 129 (1853), which incorporated the Cinque Ports with the Trinity House pilots; and all existing regulations on the subject were embodied in the Merchant Shipping Act 17 & 18 Vict. c. 104 (1854), already referred to, from which pilotage authorities within the United Kingdom derive their jurisdiction, and which regulates their powers, the licensing of pilots and their rights, privileges, liabilities, and remuneration (Maude and Pollock, *Law of Merchant Shipping*, 1861).

The laws of pilotage in the United States are regulated by the individual States according to the Acts of Congress.

PILOT-FISH (*Naucrastes ductor*), a pelagic fish of the family of Horse-Mackerels, well known to sailors from its peculiar habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and sub-tropical seas, and is common in the Mediterranean, but becomes scarcer in higher latitudes. In summer pilots will follow ships as far north as the south coast of England into port, where they are generally speedily caught. This habit was known to the ancients, who describe the

Pilot fish.

Pompius as a fish which points out the way to dubious or embarrassed sailors, and by its sudden disappearance indicates to them the vicinity of land; the ancient seamen of the Mediterranean regarded it therefore as a sacred fish. That the pilot follows sharks is an observation of much later date, which first appears in works of travel of the 17th century, the writers asserting that the shark never seizes the pilot-fish, and that the latter is of great use to its big companion in conducting it and showing it the way to its food. It is, however, extremely doubtful whether the pilot's connexion with a shark serves a more special purpose than its temporary attachment to a ship. It accompanies both on account of the supply of food which it derives from them, picking up the crustaceans, cirripeds,

¹ In a measure before parliament in 1884, but not passed, it was contemplated to wholly abolish compulsory pilotage, releasing owners or masters of ships not employing pilots from all pilotage dues or rates and from any penalty for not employing a pilot.

or other marine animals swarming about the ship's bottom or parasitic on the shark, offal thrown overboard, or smaller pieces of flesh which are left unnoticed by the shark when it tears its prey. The pilot, therefore, stands to both in the relation of a so-called "commensal," like the *Echeneis* or sucking-fish, whose habits are in some respects identical with those of the pilot, and which is frequently found associated with it. All observers, however, agree that neither the pilot nor the sucker is ever attacked by the shark. The pilot attains to a length of about 12 inches. In the shape of its body it resembles a mackerel, but is rather shorter, especially in the head, and covered with small scales. A sharp keel runs along the middle of each side of the tail. The first dorsal fin consists of a few short spines not connected by a membrane; the second dorsal and the anal are composed of numerous rays. The teeth, which occupy the jaws, vomer, and palatine bones, are all small, in villiform bands. The coloration of the pilot renders it conspicuous at a distance; on a bluish ground-colour from five to seven dark-blue or violet cross-bands traverse the body from the back to the belly. The pilot-fish spawns in the open sea, and its fry is constantly caught in the tow-net. But young pilot-fish differ considerably from the adult, having the spines of the first dorsal connected by a membrane, and some bones of the head armed with projecting spines. These little fishes were therefore long considered to be a distinct genus, *Nauclerus*.

PILPAY. See BIDPAT, vol. iii. p. 666.

PILSEN, the second town of Bohemia, lies at the confluence of the Radbusa and the Mies, 50 miles to the south-west of Prague. It consists of the town proper, which is regularly built and surrounded with promenades on the site of the old ramparts, and of three suburbs. The most prominent buildings are the Gothic church of St Bartholomew, said to date from 1292; the Renaissance town-house, containing an interesting armoury; the new real school; and the German and Bohemian theatres. The staple article of manufacture and commerce is beer, of which about 6,000,000 gallons are brewed here annually. Other industrial products are machinery, enamelled tinware, leather, alum, paper, earthenware, stoves, and spirits, while a tolerably brisk trade is carried on in wool, feathers, cattle, and horses. In the neighbourhood are several coal-pits, iron-works, and glass-works, as well as large deposits of kaolin. The four annual fairs have lost much of their former importance. The population in 1880 was 38,883, consisting of Germans and Czechs in nearly equal proportions.

Pilsen first appears in history in 976, as the scene of a battle between Otho I. and Henry V., duke of Bavaria, and it became a town in 1272. During the Hussite wars it resisted several sieges, but it was taken by Mansfeld in 1618. Wallenstein fixed his headquarters at Pilsen in 1633-34; and it was the principal scene of the alleged conspiracy which cost him his life. The first printing press in Bohemia was set up at Pilsen in 1468.

PIMENTO, also called ALLSPICE (from a supposed combination of various flavours) and JAMAICA PEPPER, is the dried immature fruit of *Eugenia Pimenta* or *Pimenta officinalis*, an evergreen tree about 30 feet high belonging to the natural order *Myrtaceæ*. It is indigenous in the West India Islands, growing on limestone hills near the sea. The spice derives its name from *pimienta*, the Spanish word for pepper, which was given to it by the early explorers of the New World from its resemblance to peppercorns. The allspice of commerce is furnished almost wholly by the island of Jamaica; and all attempts to cultivate the tree where it is not found growing spontaneously have hitherto failed. The so-called pimento walks or natural plantations from which the pimento is collected are formed by cutting down other growth upon land where

the tree grows naturally, and thus allowing it to multiply freely. The berries are gathered in July and August, when of full size, but still unripe,—the small branches bearing fruit being broken off and dried in the sun and air for some days, when the stalks are removed and the berries are ready for packing. These owe their aromatic properties to an essential oil, of which they yield on distillation from 3 to 4½ per cent. This oil has a specific gravity of 1.037, deflects the ray of polarized light 2° to the left when examined in a column of 50 millimetres, and has substantially the same composition as oil of cloves, although differing in flavour. The berries also contain a tannin (giving a black colour with ferric salts), starch, and a minute quantity of an alkaloid which, according to Dragendorff, has somewhat the odour of conia. The chief use of pimento is as a spice. The oil and distilled water are used to a limited extent in medicine to disguise the taste of nauseous drugs, and the oil is also used in perfuming soaps. The yield of some trees is said to reach as much as 150 lb of fresh or 112 lb of dried berries. The highest export reached of late years was 6,857,830 lb in 1870-71, valued at £28,574. In 1877-78 it was 6,195,109 lb. About two-thirds of the produce goes to England, and one-third to the United States. The value in the London market is about 4d. to 6d. per lb.

The fruit of an allied species, *Pimenta acris*, Wight, distinguished by the calyx being crowned with teeth, is sometimes met with in commerce. The bay rum so much used as a toilet article in the United States is a tincture flavoured with the oil of the fruit and leaves of *P. acris*, which is commonly known as the bayberry tree.

PIN. A pin is a small spike, usually of metal, with a bulbed head, or some other arrangement for preventing the spike passing entirely through the cloth or other material it is used for fastening together. In one form or another pins are of the highest antiquity, and it may be assumed that their use is coeval with human dress of any kind, the earliest form doubtless being a natural thorn, such as is still often seen fastening the dresses of peasant women in upper Egypt. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. Brooches and pins on which considerable artistic ingenuity was lavished were universally used among the civilized nations of antiquity (see BROOCH, vol. iv. p. 369). The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an Act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted, and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. His business flourished so well that he soon gave employment to 1500 persons, and Stroud pins attained a high reputation. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several

pin-making machines were invented in the United States. During the war of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836. Previous to this an American, Mr Lemuel W. Wright of Massachusetts, had in 1824 secured in England a patent for a pin-making machine, which established the industry on its present basis.

The old form of pin, which has become obsolete only within the memory of middle-aged persons, consisted of a shank with a separate head of fine wire twisted round and secured to it. The formation and attachment of this head were the principal points to which inventive ingenuity was directed. The old method of heading involved numerous operations, which had to be expeditiously accomplished, and, notwithstanding the expertness of the workers, the result was frequently unsatisfactory. Fine wire for heads was first wound on a lathe round a spit the exact circumference of the pin shanks to be headed. In this way a long elastic spiral was produced which had next to be cut into heads, each consisting of two complete turns of the spiral. These heads were softened by annealing and made into a heap for the heading boy, whose duty was to thrust a number of shanks into the heap and let as many as might be fit themselves with heads. Such shanks as came out thus headed were passed to the header, who with a falling block and die arrangement compressed together shank and head of such a number as his die-block was fitted for. All the other operations of straightening the wire, cutting, pointing, &c., were separately performed, and these numerous details connected with the production of a common pin were seized on by Adam Smith as one of the most remarkable illustrations of the advantages of the division of labour.

The beautiful automatic machinery by which pins are now made of single pieces of wire is an invention of the present century. In 1817 a communication was made at the Patent Office by Seth Hunt, describing a machine for making pins with "head, shaft, and point in one entire piece." By this machine a suitable length of wire was cut off and held in a die till a globular head was formed on one end by compression, and the other end was pointed by the revolution around it of a roughened steel wheel. This machine does not appear to have come into use; but in 1824 Wright patented the pin-making apparatus above referred to as the parent form of the machinery now employed. An extension for five years, from 1838, of Wright's patent, with certain additions and improvements, was secured by Henry Shuttleworth and Daniel Foote Tayler, and in the hands of Tayler's firm in Birmingham the development of the machine has principally taken place. In a pin-making machine as now used wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficiently wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting points are held against a revolving file-cut steel roller, along the face of which they are carried by gravitation till they fall out at the extremity well-pointed pins. The pins are next purified by boiling in weak beer; and, so cleaned, they are arranged in a copper pan in layers alternating with layers of grained tin. The contents of the pan are covered with water over which a quantity of argol (bitartrate of potash) is sprinkled, and after boiling for several hours the brass pins are coated with a thin deposit of tin, which gives them their silvery appearance. They are then washed in clean water and dried by revolving in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed finished pins.

A large proportion of the pins sold are stuck into paper by an automatic machine not less ingenious than the pin-making machine itself. Mourning pins are made of iron wire, finished by immersing in black japan and drying in a stove. A considerable variety of pins, including the ingeniously coiled, bent, and twisted nursery safety pin, ladies' hair pins, &c., are also made by automatic machinery. The sizes of ordinary pins range from the $\frac{3}{4}$ -inch stout blanket pin down to the finest slender gilt pins used by entomologists, 4500 of which weigh about an ounce. A few years ago it was estimated that in the United Kingdom there were made daily 50,000,000 pins, of which 37,000,000 were produced in Birmingham, and the weight of brass and iron wire then annually consumed was stated at 1275½ tons, of which one-eighth part was iron wire. The annual value of the whole British trade was stated at £222,000. At the same time the consumption of wire in pin-making in the United States was estimated to be from 350 to 500 tons per annum, the value of the trade being £112,000. (J. PA.)

PINDAR, the greatest lyric poet of ancient Greece whose work is represented by large remains, was born

about 522 B.C., being thus some thirty-four years younger than Simonides of Ceos. His father's name was Daiphantus; his birthplace the village of Cynoscephalæ near Thebes in Boeotia. The traditions of his family, which claimed a proud descent, have left their impress on his poetry, and are not without importance for a correct estimate of his relation to his contemporaries. The clan of the Ægeidæ—tracing their line from the hero Ægeus—belonged to the "Cadmean" element of Thebes, i.e., to the elder nobility whose supposed date went back to the days of the founder Cadmus. A branch of the Theban Ægeidæ had been settled in Achæan times at Amyclæ in the valley of the Eurotas (Pind. *Isthm.* vi. 14), and after the Dorian conquest of the Peloponnesus had apparently been adopted by the Spartans into one of the three Dorian tribes. The Spartan Ægeidæ helped to colonize the island of Thera (*Pyth.* v. 68). Another branch of the race was settled at Cyrene in Africa; and Pindar tells how his Ægid clansmen at Thebes "showed honour" to Cyrene as often as they kept the festival of the Carneia (*Pyth.* v. 75). Pindar is to be conceived, then, as standing within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean" or of Achæan stock. And the wide ramifications of the Ægeidæ throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

Pindar is said to have received his first lessons in flute-life, playing from one Scopelinus at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his use of Theban mythology, is said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrto, "for that she, a woman, contended with Pindar" (*ὄρι βὰνὰ φούσ' ἔβα Πινδάρῳ ποτ' ἔριν*)—a sentiment, it may be remarked, which does not well accord with the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (*δρχηστική*). Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyrist was required to temper into a harmonious whole (see, e.g., *Ol.* iii. 8, vi. 91, ix. 1, xiv. 15, xiii. 18; *Pyth.* xii. 23, &c.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.). He visited the court of Hiero at Syracuse; Theron, the despot of Acragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god."¹ He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

¹ Πινδάρου γένος, in ed. Ald.: ἐτιμήθη δὲ σφόδρα ὑπὸ πάντων τῶν Ἑλλήνων διὰ τὸ ὑπὸ τοῦ Ἀπόλλωνος οὕτω φιλεῖσθαι ὥς καὶ μερίθαι τῶν προσφερομένων τῷ θεῷ λαμβάνειν, καὶ τὸν ἱερέα βοᾶν ἐν ταῖς θυαῖαις Πινδάρου ἐπὶ τὸ δεῖπνον τοῦ θεοῦ.

Repute
in
Greece.

Among the Greeks of his own and later times, Pindar was pre-eminently distinguished for his piety towards the gods (*εὐσεβέστατος*, *ant. vit.*). He tells us that, "near to the vestibule" of his house (*παρ' ἐμὸν πρόθυρον*, *Pyth.* iii. 77), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the Phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Ægid ancestry, stood "where Zeus Ammon hath his seat," i.e., near the oasis and temple (*Διὸς ἐν Ἀμμωνος θεμέλοις*, *Pyth.* iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedæmonians was burning Thebes, some one wrote on Pindar's house, 'Burn not the house of Pindar the poet,' and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention.¹ Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private *ξενία* with Philip or Alexander, or by public *ξενία* with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (ii. 33, 25), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I. of Macedon. But he must have been also, or chiefly, influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.² Upwards of six hundred years after Pindar's death, the traveller Pausanias saw an iron chair which was preserved among the most precious treasures of the temple in the sanctuary at Delphi. It was the chair, he was told, "in which Pindar used to sit, whenever he came to Delphi, and to chant those of his songs which pertain to Apollo."

Pindar
and
Athens.

During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Æschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (*παῖδες Ἀθηναίων ἐβάλοντο*

φαινὸν κρηπὶδ' ἐλευθερίας, fr. 77, Bergk, 4th ed.), while Athens itself is thus invoked:—*ὦ τὰι λιπαραὶ καὶ ἰσοτέφανοι καὶ ἀοίδιμοι*, Ἑλλάδος ἔρεισμα, κλειναὶ Ἀθῆναι, δαυμόνιον πολίεθρον. Isocrates, writing in 353 B.C., states that the phrase Ἑλλάδος ἔρεισμα, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of *προξενία* (i.e., appointed him honorary consul, as it were, for Athens at Thebes), besides presenting him with a large sum of money (*Antid.* § 166). One of the letters of the pseudo-Æschines (*Ep.* iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum.³ The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (i. 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth.* i. 75). In celebrating the Pythian victory of the Athenian Megacles, he begins thus:—"Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear?" Referring to the fact that an Æginetan victor in the games had been trained by an Athenian, he says—*χρὴ δ' ἀπ' Ἀθανῶν τέκτον' ἀθληταῖσιν ἔμμεν* (*Nem.* v. 49); "meet it is that a shaper of athletes should come from Athens"—where, recollecting how often Pindar compares the poet's efforts to the athlete's, we may well believe that he was thinking of his own early training at Athens under Lasus of Hermione.

Pindar's versatility as a lyric poet is one of the Works, characteristics remarked by Horace (*Carm.* iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

1. ὕμνοι, *Hymns* to deities—as to Zeus Ammon, to Persephone, *Fragmentary Hymns* entitled *Θεβαῖοι* seems to have celebrated the deities of Thebes. 2. *Παιᾶνες*, *Pæans*, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis, or Zeus. 3. *Διθύραμβοι*, *Dithyrambs*, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus (cp. Pind., *Ol.* xiii. 18, *ταὶ Διονύσου πόθεν ἐξέφανε σὺν βοηλάτῃ Χάριτες διθύραμβον*,—where Pindar alludes to the choral form given to the dithyramb, *circa* 600 B.C., by Arion,—*βοηλάτης*, "ox-driving," perhaps meaning "winning an ox as prize"). 4. *Προσόδια*, *Processional Songs*, choral chants for worshippers approaching a shrine. One was written by Pindar for the Delians, another for the Æginetans. 5. *Παρθένια*, *Choral Songs for Maidens*. The reference in Pind. *Pyth.* iii. 77 to maidens worshipping Cybele and Pan near the poet's house is illustrated by the fact that one of these *Παρθένια* invoked "Pan, lord of Arcadia, attendant of the Great Mother, watcher of her awful shrine" (fr. 95, Bergk). 6. *ἑορτήματα*, *Choral Dance-Songs*, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (107), written for the Thebans in connexion with propitiatory rites after an eclipse of the sun, probably that of April 30, 463 B.C. 7. *ἑγκώμια*, *Songs of Praise* (for men, while *ὕμνοι* were for gods), to be sung by a *κῶμος*, or festal company. In strictness *ἑγκώμιον* was the genus of which *ἐπινίκιον* was a species; but the latter is more conveniently treated as a distinct kind. Pindar wrote encomia for Theron, despot of Acragas, and for Alexander I. (son of Amyntas), king of Macedon. 8. *Σκόλια*, *Festal Songs*. The

¹ Schaefer, *Demosthenes und seine Zeit*, iii. 119.

² It will be remarked that history requires us to modify the statement in Milton's famous lines:—

"The great Emathian conqueror bade spare
The house of Pindarus, when temple and tower
Went to the ground."

Indeed, the point of the incident depends much on the fact that the temples and Pindar's house were classed together for exemption.

³ Compare Jebb, *Attic Orators*, vol. ii. p. 143.

usual sense of *σκόδιον* is a drinking-song, taken up by one guest after another at a banquet. But Pindar's *σκόδια* were choral and antistrophic. One was to be sung at Corinth by a chorus of the *ἱερόδουλοι* attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character. 9. *Θρήνοι, Dirges*, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class (129-133). One of the smaller fragments (137)—in memory of an Athenian who had been initiated into the Eleusinian mysteries (*ἰδῶν κείνα*)—has been conjecturally referred to the *Θρήνοι*; which Pindar is said to have written (schol. *Pyth.* vii. 18) for Hippocrates, the grandfather of Pericles. A number of small fragments, which cannot be certainly classified, are usually given as *ἐξ ἀδήλων εἰδῶν*, "of uncertain class." On comparing the above list with Horace, *Carm.* iv. 2, it will be seen that he alludes to No. 3 (*dithyrambos*); to Nos. 1, 2, and 7 (*seu deos regere canit*); and to No. 9 (*flebili sponssæ juvenemve raptum Plorat*),—as well as to the extant *Epinicia* (*sive quos Elea domum reducit Palma caelestes*).

The
extant
odes.

The Epinicia.—The *ἐπινίκια* (sc. *μέλη*), or *ἐπινίκιοι* (sc. *ῥυμοι*), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals:—(1) *Ὀλυμπιονίκαι* (sc. *ῥυμοι*): fourteen odes for winners of the wild olive-wreath in the Olympian games, held at Olympia in honour of Zeus once in four years; (2) *Πυθιονίκαι*: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) *Νεμεονίκαι*: seven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) *Ἰσθμιονίκαι*: eleven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. plur. followed by the numeral, e.g., "the ninth Olympian" is *Ὀλυμπιονίκαι θ'*. The chronological range of the collection (so far as ascertainable) is from 502 B.C. (*Pyth.* x.) to 452 B.C. (*Ol.* v.). With respect to the native places of the victors, the geographical distribution is as follows:—for the mainland of Greece proper, 13 odes; for Ægina, 11; for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

The general characteristics of the odes may be briefly considered under the following heads:—(1) language; (2) treatment of theme; (3) sentiment—religious, moral, and political; (4) relation to contemporary art.

Language.

1. The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness. Thus (a) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called *εἰδανὸν φάρμακον αἰρᾶν* (*Ol.* ix. 104), "a warm remedy for winds." (b) Images for the highest excellence are drawn from the furthest limits of travel or navigation, or from the fairest of natural objects; as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (*Isthm.* ii. 42); or when Olympia, the "crown" (*κορυφά*) or flower (*ἄνθος*) of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (*Ol.* i. *ad init.*). This trait might be called *the Pindaric imagery of the superlative*. (c) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (*Pyth.* v. 56). (d) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone,

mixing wine in a bowl, and many more. (e) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the *συντάλη* or secret despatch, &c. And we have such homely proverbs as, "he hath his foot in this shoe," i.e., stands in this case (*Ol.* vi. 8). (f) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (g) Words not found except in Pindar are numerous, many of these being compounds which (like *ἐναρίμβροτος*, *καταφυλλοροεῖν*, &c.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "bold dithyrambs."

2. The actual victory which gave occasion for the ode is seldom treated at length or in detail,—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilas, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes,—(as the birth of Iamus (*Ol.* vi), or the vision of Bellerophon (*Ol.* xiii),—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn, *καί τινα ὄμιον ἱσάμι βραχύν* (*Pyth.* iv. 247). It has been thought that, in the parenthesis about the Amazons' shields (*quibus Mos unde deductus . . . quærevæ distuli*, *Carm.* iv. 4, 17), Horace was imitating a Pindaric transition; if so, he has illustrated his own observation as to the peril of imitating the Theban poet.

3. (a) The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they are ordained with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz., that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as *Ol.* ii. 66 sq.). Pindar was familiar with the idea of metempsychosis (cp. *ib.* 83), but the attempt to trace Pythagoreanism in some phrases (*Pyth.* ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the *Θρήνος* (no. 137, Bergk), we may probably regard the mystic or esoteric element in Pindar's theology as due to such a source.

(b) The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (*φύνη*) is the grand source of all human excellence (*ἀρετή*), while such excellences as can be acquired by

Treat-
ment of
theme.

Senti-
ment of
the odes
—re-
ligious;

study (*διδασκαλὶ ἀρεταί*, *Ol.* ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of *εὐγίης ὄλβος*—"sane happiness," such as has least reason to dread the jealousy of the gods, —are substance sufficing for daily wants and good repute (*εὐλογία*). He who has these should not "seek to be a god." "Wealth set with virtues" (*πλοῦτος ἀρεταῖς δεδαιδαλμένος*), as gold with precious gems, is the most fortunate lot, *because* it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (cp. *Pyth.* ii. 83; *Isthm.* iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

political. (c) The political sentiments of the Theban poet are suggested by *Pyth.* xi. 53; "In politics I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in *Pyth.* ii. 86 a democracy is described as *ὁ λάβρος σπαραγός*, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (*δλιγαρχία ἰσόνομος*, *Thuc.* iii. 62) had replaced the narrower and less temperate oligarchy of former days (*δυναστεία οὐ μετὰ νόμων*); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol.* i. 113); he sketches the character of an ideal king (*Pyth.* iii. 71); but nothing in his poetry implies liking for the *τυραννίς* as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours "Tranquillity, the friend of cities" (*Ἀσυχία φιλόπολις*, *Ol.* iv. 16). The epic poet sang of wars; Pindar celebrates the "rivalries of peace."

Relation to contemporary arts. 4. Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (*τόλμα δὲ καὶ ἀμφιλαφὴς δύναμις ἔσποιοιτο*, *Ol.* ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase *δαιδάλλειν*, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the Hours is opened, and delicate plants perceive the fragrant spring" (fr. 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 194); in the lines on the eclipse of the sun (fr. 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable, —as in the beautiful story of the birth of Iamus—when

Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

The spirit of art, in every form, is represented for Pindar by *χάρις*—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The Sculpture period from 500 to 460 B.C., to which most of Pindar's extant odes belong, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon, and Ægina were effecting a transition from archaic types to the art which was afterwards matured in the age of Phidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards, sculpture had been applied to the commemoration of athletes, chiefly at Olympia. In a striking passage (*Nem.* v. *ad init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Ægina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Ægina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigan-tomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithæ, and (6) a contest between Heracles and Apollo are instances of mythical material treated alike by the poet and by sculptors of his day. The contemporary improvements in town architecture, introducing spacious and well-paved streets, such as the *σκυρωτή ὁδός* at Cyrene (*Pyth.* v. 87), suggest his frequent comparison of the paths of song to broad and stately causeways (*πλατεῖαι πρόσοδοι—ἐκατόμπεδοι κέλευθοι*, *Nem.* vi. 47, v. 22). A song is likened to cunning work which blends gold, ivory, and coral (*Nem.* vii. 78). Pindar's feeling that poetry, though essentially a divine gift, has a technical side (*σοφία*), and that on this side it has had an historical development like that of other arts, is forcibly illustrated by his reference to the inventions (*σοφίσματα*) for which Corinth had early been famous. He instances (1) the development of the dithyramb, (2) certain improvements in the harnessing and driving of horses, and (3) the addition of the pediment to temples (*Ol.* xiii.).

In the development of Greek lyric poetry two periods are Pindar's broadly distinguished. During the first, from about 600 place in Greek literature to 500 B.C., lyric poetry is local or tribal—as Alcæus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker*. The Greeks usually spoke, not of "lyric," but of "melic" poetry (*i.e.*, meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyrist. Epic, lyric, and dramatic poetry succeeded each other in Greek litera-

ture by a natural development. Each of them was the spontaneous utterance of the age which brought it forth. In Pindar we can see that phase of the Greek mind which produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Æschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

Manu-
scripts
and
editions.

The fact that certain glosses and lacunæ are common to all our MSS. of Pindar make it probable that these MSS. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (*circa* 15 B.C.), sometimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (160 A.D.). The archetype of our MSS., then, cannot have been older than the end of the 2d century. Our MSS. fall into two general classes:—(1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.-xii.; Mediceus 2; and Vaticanus 2,—the two last-named being of the highest value. The *editio princeps* is the Aldine, Venice, 1518. A modern study of Pindar may be almost said to have begun with Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But Augustus Boeckh (1811-22), who was assisted in the commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poet. Lyr.*) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to MSS. A recension by W. Christ has been published in Teubner's series (1879). The edition of J. W. Donaldson (Cambridge, 1841) has many merits; but that of C. A. M. Fennell (Cambridge, 1879-83) is better adapted to the needs of English students. The translation into English prose by Ernest Myers (2d ed., 1883) is excellent. Pindar's metres have been analysed by J. H. Schmidt in *Die Kunstformen der Griechischen Poesie* (Leipzig, 1868-72). For estimates of Pindar see the histories of Greek literature by G. Bernhardt, K. O. Müller, Nicolai, and E. Burnouf. (R. C. J.)

PINE (*Pinus*, Gr. *πίκνυς*), a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus of true conifers (*Abietinæ*), differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membranous sheath, either in pairs or from three to five together,—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature—as in the allied genera.

The pines are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which, in Central America, a few are found within the tropic; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. Their soft, straight-grained,

resinous, and often durable wood gives to many kinds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris*, the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 feet, it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top, with a straight trunk of from 2 to 4 feet in diameter at the base, and gnarled twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often

FIG. 1.—Scotch Fir (*Pinus sylvestris*). a, male flower and young cones; b, male catkin; c, d, outer and inner side of anther-scale.

twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and fecundate the purple female flowers, which, at first sessile and erect, then become recurved on a lengthening stalk; the ovate cones, about the length of the leaves, do not reach maturity until the autumn of the following year, and the seeds are seldom scattered until the third spring; the cone scales terminate in a pyramidal recurved point, well-marked in the green state and in some varieties in the mature cone, but in others scarcely projecting. *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest-slopes of Etna, while in longitude its range extends from the shores of the North Sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula, this tree is the true fir (*fur*, *fura*) of the old Norsemen, and still re-

tains the name among their descendants in Britain, though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground, and is found even at an elevation of 700 feet, while in south Norway it occurs up to 3000 feet, though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the south-eastern dales; in the highest situations it dwindles to a mere bush. In Germany, both on the mountains and the sandy plains, woods of "kiefer" are frequent and widely spread, while vast forests in Russia and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of Dahuria; on the European Alps it occurs at a height of 5600 feet, and on the Pyrenees it is found at still higher elevations; on the northern side of Etna it is

FIG. 2.—Scotch Fir (*Pinus sylvestris*). *a*, fertile flower of mature cone; *b*, winged seed; *c*, fertile catkin (or cone); *d*, scale and bract; *e*, inner side of scale.

said to grow at above 7000 feet. In Britain natural forests of Scotch fir of any extent are only now found in the Highlands, chiefly on the declivities of the Grampians, and most of the great woods have been much curtailed in recent times, while the larger trees are generally felled as soon as they attain a timber size. In former ages the tree covered a large portion of the more northern part of the island, as well as of Ireland; the numerous trunks found everywhere in the mosses and peat-bogs of the northern counties of England attest its abundance there in prehistoric times; and in the remoter post-Glacial epoch its range was probably vastly more extended. The tree is not at present indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus formed during the last fifty years. The Scotch fir is a very

variable tree, and certain varieties have acquired a higher reputation for the qualities of their timber than others; among those most prized by foresters is the one called the Braemar pine, the remaining fragments of the great wood in the Braemar district being chiefly composed of this kind; it is mainly distinguished by its shorter and more glaucous leaves and ovoid cones with blunt recurved spines, and especially by the early horizontal growth of its ultimately drooping boughs; of all varieties this is the most picturesque. On the Continent the Hagenau pine of Westphalia is esteemed for the straightness and good quality of its timber. The heart-wood of the finer kinds of Scotch fir is of a deep brownish-red colour, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps little inferior; from its lightness and elasticity it is well adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb the cubic foot. The sap-wood is more perishable, but is useful for fences, casks, and a variety of other purposes; soaking in lime-water renders it more lasting; great numbers of young pines are annually cut for railway sleepers, mining timber, and numerous agricultural applications; large quantities are consumed in forming the wood-pavement which in the great towns is rapidly superseding stone. The quality of the timber depends greatly on the soil and position in which the trees are grown: the dry slopes of granitic or gneissic mountains, or the deep well-drained sandy gravels of the lower country seem to answer equally well; but on clay or wet peat the tree rarely flourishes, and the timber is always indifferent; it is usually said that the wood is best in the cold climate of its more northern habitats, but the writer has seen a trunk (4 feet in diameter) grown on the sands of Surrey with heart-wood quite equal to any produced in Glenmore or Rothiemurchus. The rapidity of growth is still more variable: in Britain full maturity is attained in from seventy to one hundred and twenty years, but in Norway the trunk increases much more slowly; Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 feet 10 inches in diameter without the bark, showed four hundred circles of annual growth. In Norway the tree, growing in dense forests, is generally of but moderate girth, and probably this pine nowhere reaches a greater size than in the Scottish woods; a plank from Glenmore forest measured nearly 5½ feet across, and from 3 to 4½ feet is not an unusual diameter for a British pine tree.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct from the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of Scotch fir requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, excepting for the removal of dead wood. Plantations in England are generally ready for final cutting in from sixty to seventy years, and many are cleared at a much earlier stage of growth. *P. sylvestris* in Britain is liable to many insect depredations: the pine-chaffer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; *Hylobius abietis*, the fir-weevil, eats away the bark, and numerous lepidopterous larvæ devour the leaves; the pine-sawfly is also injurious in some seasons; the removal of all dead branches from the trees and from the ground beneath them is recommended as most of these

insects lay their eggs among the decaying bark and dead leaves. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species. As fuel the wood of the Scotch fir is of value, but it makes too much black smoke to form an agreeable open fire; the small trunks and cuttings of plantations are employed by the lime-burner.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks, and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *walchvolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. pumilio*, the "krumholz" or "knieholz" of the Germans,—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser, and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tyrolean Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit. Krumholz oil, valued in Germany as an outward application in rheumatism and for bruises and sprains, is distilled from the young branches, and a fragrant white resin that exudes in some quantity from the buds is used for similar purposes and as a perfume; under the name of Hungarian balsam it is sold in the towns of Germany, being probably obtained from the Carpathians.

The Red Pine of Canada and New England (so called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 inches long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in shipbuilding; according to Emerson, trunks exist in Maine 4 feet in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the Grey or Labrador Pine, some-

times called the Scrub Pine from its dwarfish habit; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 inches long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

P. Laricio, the Corsican Pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 feet, with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 inches long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The Black Pine, *P. austriaca*, derives its name from the extreme depth of its foliage tints,—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree. The light-coloured, glossy, horizontal cones are generally in pairs, but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain. The leaves are long and of a light bright green; the cones are solitary, oblong, conical, and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality. In plantations its bright foliage, with the orange cones and young shoots, render it an ornamental tree, hardy in southern Britain. Near to the above are *P. Pallasiana* or *maritima*, and *P. halepensis*, Mediterranean forms chiefly valued for their resinous products; the former, planted on the loose sands of France, supplies much turpentine and resin.

P. Pinaster, the Cluster Pine or Pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 70 feet, the deeply-furrowed trunk occasionally reaches a diameter of 3 feet or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 inches long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions. *P. brutia*, the Calabrian Pine, a kindred form, is remarkable for its numerous densely clustered radiating cones; its wood is considered good in southern Italy.

P. Pinea is the Stone-Pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful

reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 feet in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the Yellow Pine of the northern and middle States of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 feet and upwards, though rarely more than 2 feet in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ inches long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in shipbuilding and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the Pitch-Pine of the northern States, a tree of from 40 to 50 feet in height with rugged trunk, occasionally 3 feet in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. australis is the "Georgia Pitch-Pine," or Yellow Pine of the southern States; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence it is sometimes called *P. palustris*. The most marked feature of the tree is its long tufted foliage,—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the States; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West India Islands. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. taeda, the "Loblolly Pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern States, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 feet high, having sometimes a girth of 6 or 8 feet, with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, a pine of western America belonging to this section, is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri*, or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 inches in diameter, and weighing more than 4 lb); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniiana*, the Nut-Pine of California, the cones of which are of nearly equal size, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 feet and upwards, while trunks have been found, it is said, 10 or 12 feet in diameter. *P. longifolia*, a Nepal species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "Cheer-

Pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, another Nepal species, is a large tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer-pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 feet, also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey-Pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three or four; the lower cone-scales have recurved points. This fine pine has been planted in the south-western parts of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known White Pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of American trees. The tree abounds from Canada to Georgia, and is also found in British Columbia, but in the eastern States has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England; one that stood near the banks of the Merrimack in New Hampshire is said to have had a trunk nearly 8 feet in diameter, and Michaux measured a stump 6 feet across. On a deep rich soil *P. Strobus* attains a height of 150 or even 200 feet, and trunks without a branch are sometimes found 80 or 90 feet long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 inches in length and 1½ to 2 inches broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 lb per cubic foot. In England, where it is generally known as the "Weymouth Pine," it succeeds well on deep light soils when well-drained; trees have attained occasionally a height of 100 feet and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well; a tree at Berlin measured upwards of 3 metres in circumference, the age being one hundred and fifty years. The climate of Scotland appears less suitable for it, probably from the want of summer heat, and it can hardly be recommended for British planting otherwise than for ornamental purposes.

Nearly approaching this is *P. excelsa*, the Bhotan Pine, which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhotan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 6000 to 7000 feet, and attains large dimensions; the wood is highly resinous, and is said to be durable; great quantities of a white clear turpentine exude from the branches when injured. The Bhotan pine is quite hardy in southern England, and has been largely planted of late as an ornamental tree.

P. Lambertiana, the Giant Pine or Sugar-Pine of California, is the largest of the genus, rising to the height of 200 feet, with a trunk 20 to 30 feet in girth, and, it is said, occasionally attaining much larger dimensions. The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce; its foliage is of a light bright green colour. The pendent cones are very large, sometimes 18 inches long and 4 inches in diameter, with large nut-like seeds, which, pounded and baked, are eaten by the Indians. The tree abounds in some sandy districts, but more generally occurs singly or in small groups dispersed through the woods, attaining its greatest dimensions in light soils. The wood is soft and nearly white, but contains much resin, which when fire has run through the forest exudes, and, having in this half-burnt condition a sweetish taste, has given the common name to the tree; the wood seems to be formed slowly; from its smooth grain it is valued for indoor carpentry; the saccharine burnt resin is used as a laxative in California.

P. Cembra is the Stone-Pine of Siberia and central Europe. It abounds on the Alps, the Carpathians, and the Siberian ranges, in Switzerland being found at an altitude of 6800 feet in some localities. It is a straight-growing tree, with grey bark and whorls of horizontal branches, growing often from the ground, giving a

cylindro-conical outline; the leaves are short, rigid, and glaucous; the cones, oblong and rather pointing upwards, grow only near the top of the tree, and ripen in the second autumn; the seeds are oily like those of *P. pinea*, and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed from them which is used both for food and in lamps, but, like that of the Italian pine, it soon turns rancid. The growth of *P. Cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood-carvers in preference to any other. The *Cembra* is the "zirbel" or "zirbel-kiefer" of the Germans, and is known locally in Switzerland as the "arolle," "aloies," and "arve."

P. occidentalis, a five-leaved pine with pale green foliage and small ovate cones, is found on the high mountains of St Domingo. Many members of the group occur on the Mexican isthmus, one of which, *P. cembroides*, produces edible seeds. *P. Ayacahuite*, a large tree growing on the mountains of Guatemala, with glaucous foliage like *P. Strobus*, yields a valuable resin. *P. filifolia* and *P. macrophylla*, likewise natives of Central America, are remarkable for the extreme length of their leaves; the former is said to attain a large size. (C. P. J.)

PINE-APPLE. The pine-apple so-called consists in reality of the inflorescence of the plant, the originally separate flowers of which, together with the bracts supporting them, become fleshy and consolidated into one mass. The swelling and fusion of the tissues take place after the process of fertilization, and it may be that the richly perfumed succulent mass is an aid in the distribution of seed by affording food to certain animals. In the highly developed cultivated pines, however, it frequently happens that the seeds do not ripen properly. The pine, *Ananassa sativa*, is a member of the Bromeliad family, supposed to be of tropical American origin, and has been found wild in Mexico, Central America, Guiana, and Brazil, but is now widely dispersed in all tropical and semitropical countries.

Evelyn in his *Diary* mentions tasting a pine-apple from Barbados at the table of Charles II., and this is we believe the first mention of the fruit in English literature. A picture, of which a copy may be seen at the rooms of the Royal Horticultural Society of London, represents the royal gardener, Mr Rose, presenting on bended knee the first pine-apple grown in Britain, and it is surmised that this may have been grown from the "suckers" of the fruit above alluded to by Evelyn, though it is generally considered that the pine was not cultivated in England till 1712. In spite of the great improvements in the quality of pines, and the great progress that has been brought about in the rapidity and facility of production, pine-growing is still attended with considerable expense, and much expenditure of time and labour. At the same time great attention has been given to pine culture in the West India Islands, the Azores, &c., and very large quantities of fruit of fine quality are imported into Britain at relatively low prices. But for pines of the highest flavour in the winter and spring seasons Englishmen must still look to their own gardens. See **HORTICULTURE**.

PINEL, PHILIPPE (1745-1826), a distinguished French physician, was born at the chateau of Rascas, Saint-André, in the department of Tarn, France, on April 20, 1745. He studied at Lavaur and afterwards at the university of Toulouse, where he took his doctor's degree in 1773. From Montpellier, where he taught mathematics and at the same time carried on his medical studies, he removed in 1778 to Paris, engaging there chiefly in literary work connected with his profession. His first publication was a French translation of Cullen's *Nosology* (1785); it was followed by an edition of the works of Baglivi (1788), and in 1791 he published a *Traité medico-philosophique de l'alienation mentale*. In 1792 he became head physician of the Bicêtre, and two years afterwards he received the corresponding appointment at the Salpêtrière, where he began to deliver a course of clinical lectures; these formed the basis of his *Nosographie philosophique* (1798; 6th ed. 1818), which was further developed in *La Médecine*

clinique (1802). Pinel was made a member of the Institute in 1803, and soon afterwards was appointed professor of pathology in the École de Médecine. Neither as a lecturer nor as an author, however, did he achieve great success, and his enduring fame rests entirely upon the fact that by his courageous action he was among the first to introduce the humane treatment of the insane, removing with his own hands the bonds of patients who had been chained to the wall for years. See vol. xiii. p. 110. He died at Paris on October 26, 1826.

PINEROLO, a city of Italy, in the province of Turin (Piedmont), is built in a straggling manner on a hill-side just above the junction of the valleys of the Chisone and the Lemina, at a height of 1237 feet above the sea, 23½ miles by rail south-west of Turin. It is the terminus of the branch railway from Turin by Sangone or Nichellino, and has steam tramways running up to Perosa (12 miles) and south to Saluzzo. Till 1696 it was strongly fortified with a citadel on Santa Brigida, a castle on St Maurizio, and city walls constructed by Thomas I. of Savoy. It has a cathedral (St Donatus), a bishop's palace, a large seminary, a theatre (1842), a hospital (1546), a public library, a cavalry college, a school of music, and a Waldensian chapel and schools. Cotton, silk, wool, and hemp are among the local manufactures. The population of the city was 11,362 in 1871 and 12,003 in 1881 (commune 16,730 and 17,492).

Pinerolo was bestowed on the bishops of Turin by Otho III. in 996; but in 1078 the countess Adelaide made it over to the Benedictine abbey of Santa Maria, in whose possession it remained till 1159. Thomas I. of Savoy captured the castle in 1188, and in 1246 the commune formally recognized the supremacy of Savoy. Passing in 1295 into the hands of Philip, son of Thomas III., Pinerolo became his residence and capital, a distinction which it retained under Amadeus VIII. of Savoy, even after the extinction of the separate house of Piedmont in 1418. Francis I. of France obtained possession of the town in his descent into Italy, and tried to secure the allegiance of the people by relieving the woollen trade from taxation; but Emmanuel Philibert received it back from Henry III. in 1574. A second occupation by the French occurred under Cardinal Richelieu: the French language was imposed on the people, great fortifications were constructed, and the fortress was used as a state prison for such men as Fouquet, De Caumont, and the Man with the Iron Mask. Victor Amadeus bombarded the place in 1693, and ultimately compelled Louis XIV. to relinquish his hold on it; but before the withdrawal of the French troops the defences were demolished and the military importance of Pinerolo brought to a close. In 1748 the town was made a bishop's see. Michele Buniya, pensioned by Victor Emmanuel I. as the introducer of vaccination into Piedmont, was a native of Pinerolo and has a statue in the Piazza del Palazzo. De Grossi and Massi are among the local historians.

PINK. As usually applied this word corresponds to a genus of *Caryophyllaceæ*, the *Dianthus* of botanists. It is characterized by the presence of opposite simple leaves, proceeding from thickened nodes, a cymose inflorescence, a tubular calyx surrounded by a number of overlapping bracts, a showy corolla of five free long-stalked petals, ten stamens proceeding, together with the petals, from a short stalk supporting the ovary, which latter has two styles and ripens into an oblong pod which splits by two valves. The species are herbaceous or perennial, of low stature, often with very showy flowers. They are natives chiefly of southern Europe and the Mediterranean region, a few being found in temperate Asia and South Africa. One species only is native to America, and that only in the north-west. Four species are wild in Britain, with two others which are more or less naturalized. These two are the more interesting as being the originals of the pinks and of the carnations and picotees of English gardens. Garden Pinks are derivatives from *Dianthus plumarius*, a native of central Europe, with leaves rough at the edges, and with rose-coloured or purplish flowers. The use of "pink" to denote a colour is derived from the name of the plant.

The Carnation and Picotee are modifications of *Dianthus Caryophyllus*, the Clove Pink, a species with smooth edges to the leaf. This is a native of Europe, growing on rocks in the south, but in the north usually found on old walls. Its occurrence in England on some of the old Norman castles, as at Rochester, is supposed by Canon Ellacombe to indicate its introduction by the Normans; in any case the plant grows in similar situations in Normandy. The original species has "self"-coloured flowers, that is, flowers of one hue, generally some shade of pink, but the variations in gardens are infinite. The carnation includes those flowers which are streaked or striped lengthwise—the picotees are those in which the petals have a narrow band of colour along the edge, the remainder of the petal being free from stripes or blotches. These by the old writers were called "gillyflowers" (see vol. x. p. 601). The Sweet William of gardens is a product from *Dianthus barbatus*; the Indian Pink comes from *D. sinensis*, of which *D. Heddewigii* is a variety; the Alpine Pink, *D. alpinus*, is a very lovely plant for the rockery; and there are many hybrid and other varieties met with in gardens, for an account of which reference must be made to treatises on horticulture.

PINKERTON, JOHN (1758–1826), archæologist, numismatist, historian, geographer, and miscellaneous writer in prose and verse, was born at Edinburgh, February 17, 1758. After a brief education at Lanark he was articled as a law clerk in Edinburgh, his earliest work, printed during his clerkship, being an *Elegy on Craigmillar Castle* (1776). In 1780 he removed to London to devote himself to literary work, publishing in 1781 a volume of *Rimes* of no great merit, and a professed collection of *Scottish Tragic Ballads*. These were followed in 1782 by *Two Dithyrambic Odes on Enthusiasm and Laughter*, and by a series of *Tales in Verse*. Under the title of *Select Scottish Ballads* he reissued in 1783 his tragic ballads, with a supplement comprising *Ballads of the Comic Kind*,—a collection which obtained for him the not wholly appropriate title of "the second Chatterton." An *Essay on Medals* in 1784 won him a considerable reputation, which was in some respects unpleasantly maintained by his bold but eccentric *Letters on Literature* published in 1785 under the pseudonym of Robert Heron—a temporary adoption of his mother's surname. In the following year he edited the *Ancient Scottish Poems from the MS. Collections of Sir Richard Maitland of Lethington*,—a genuine reproduction, though his confession in the preface of forgery in the previous collections published by him brought groundless suspicion upon it. It was succeeded in 1787 by a compilation, under the new pseudonym of Bennet, entitled the *Treasury of Wit*, and by his first important historical work, the *Dissertation on the Origin and Progress of the Scythians or Goths*, to which Gibbon professed himself indebted. Turning his attention to hagiology, Pinkerton next collected and printed in 1789 certain *Vite Sanctorum Scotiæ*, and, a little later, published his *Enquiry into the History of Scotland preceding the Reign of Malcolm III.*, in which he hoped to settle the ancient history of his country on the solid footing of facts and authorities and "leave nothing in the ink horn." In many quarters his attitude towards the Highlanders excited "violent disgust," but the *Enquiry* was twice reprinted, in 1794 and 1814, and is still of value for the documents embodied in it. His edition of Barbour's *Bruce* and a *Medallic History of England to the Revolution* appeared in 1790; a collection of *Scottish Poems reprinted from scarce Editions* in 1792; and a series of biographical sketches, the *Iconographia Scotica*, in the years 1795–97. In the last-mentioned year he published a *History of Scotland from the Accession of the House of Stuart to that*

of Mary, containing valuable material, but almost entirely devoid of literary finish. A new biographical collection, the *Gallery of Eminent Persons of Scotland* (1799), was succeeded after a short interval by a *Modern Geography digested on a New Plan* (1802; enlarged, 1807). About this time he left London for Paris, where he chiefly resided until his death on May 10, 1826. His remaining publications were the *Recollections of Paris in the years 1802–3–4–5* (1806); a very useful *General Collection of Voyages and Travels* (1808–1813); a *New Modern Atlas* (1809–15); and his *Petralogy* (1811). An unsuccessful tragedy by him was performed at Edinburgh in 1813.

Pinkerton possessed an exceedingly vigorous and acute mind, but very lacking in high constructive power; and, as he was less patient in the formation of opinion than in research, his best work is marred by imperfect judgments crudely and obstinately asserted. At the same time his writings take no mean rank in the advance towards a scientific treatment of history. Walpole, notes of whose conversations were published at his death by Pinkerton under the title of *Walpoliana*, regarded his understanding as "one of the strongest, most manly, and clearest he ever knew;" and Gibbon not only praised his faculty of persistent application as herculean and heroic, but wished to secure his co-operation in a scheme for organizing the materials of early English history. The final verdict upon his work must be that of the Earl of Buchan, who endorsed Pinkerton's statement that he was "a *homo umbratilis*, of a hypochondriac unsocial disposition," with the comment "*se ipse dixit*: it is his best apology; yet undoubtedly he has been a benefactor to literature."

PINSK, a district town of the government of Minsk, Russia, is situated in a marshy region at the confluence of the Strumeñ and Pina rivers, 172 miles to the south-west of Minsk. It has a lyceum, several primary schools, and a great number of Jewish schools. The town is almost entirely built of wood, and has a poor appearance. The population (13,000 in 1865) was in 1884 22,950, more than four-fifths of whom are Jews, who live almost exclusively on trade. This development of trade in a town situated at a distance from all railways (the nearest, that from Moscow to Warsaw, being 60 miles off) is due to the navigable river Pina, which connects it with the fertile regions on the Dnieper, and, by means of the Dnieper-and-Bug Canal, with Poland and Prussia, while the canal of Oginsky connects it with the basin of the Niemen. The merchandise brought from the Dnieper is unshipped at Pinsk, and sent west or north-west on smaller vessels.

Pinsk (Pinesk) is first mentioned in Russian annals in 1097 as a town belonging to Sviatopolk, prince of Kieff. In 1182 it formed part of the Minsk principality, and it often changed its rulers subsequently. After the Mongol invasion it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was recognized as chief town of the province of Brest. During the rebellion of Bogdan Khmelnitzky (1640), as it had fallen into the hands of the Cossacks, the Poles took it by assault, destroying 14,000 persons, and burning 5000 houses. Eight years later the town was burned again by the Russians. Charles XII. took it in 1706, and when compelled to quit, burned the palace of Prince Wiszniewski, and the town with its suburbs. Pinsk was annexed to Russia in 1795.

PINTO, FERNÃO MENDES (1509(?)–1583), a noted Portuguese adventurer, was born in 1509 or 1510 at Montemor-o-Velho, near Coimbra, and died near Lisbon, July 18, 1583. After spending some years in Lisbon and Setubal, and experiencing various adventures, he left his native country in 1537, in a fleet of five ships, committing himself to a career of adventure at sea, which lasted twenty-one years, in the course of which he was five times shipwrecked, thirteen times taken captive, and seventeen times sold as a slave. If Pinto's own narrative is coloured in many passages by a wandering and fervid imagination, its substantial honesty is now generally admitted, in spite of Congreve's opprobrium in *Love for Love*,—"F. M. Pinto was but a type of thee, thou liar of the first magnitude." The fleet with which Pinto left

Portugal anchored, after various adventures, at Socotra, and he himself was taken captive near the Straits of Babelmandeb, carried to Mocha, sold as a slave, and ransomed by the Portuguese governor of Ormuz. Returning to the Indies, he was again engaged in several expeditions, again enslaved, again ransomed, and again captured by pirates. In 1542 he was engaged in an expedition to Calempin, near Peking, to rifle the tombs of seventeen Chinese kings. Shipwrecked and captured on the Chinese coast, he was set to work in repairing the Great Wall, whence an inroad of Tartars transported him to the siege of Peking and next to Tartary. Hence we follow him to Cochinchina, Macao, and Japan. At Ningpo his report of Japan and its wealth caused the equipment of nine ships, eight of which foundered, Pinto's ship being driven to the Lew-chew Islands. After a variety of other adventures, Pinto returned a third time to Japan with Francis Xavier in 1548. In 1553, while at Goa on his return to Portugal with his rich fortune, he was induced to devote nearly all his wealth to the foundation of a seminary for propagating the faith in Japan. Returning to Lisbon in 1558, he spent a few years at court, but found the life very stale after his stirring adventures in the East.

The first extant account of his adventures is to be found in a collection of Jesuits' letters published in Italian at Venice in 1565. The full narrative, however, of his life is his own *Peregrinação*, which was first published in quarto at Lisbon in 1614 by Francisco de Herrera. In 1620 appeared a Spanish translation, and in 1628 at Paris a French translation by B. Figuer, followed by two other editions (1645 and 1830). There is also an English translation by H. Cogan (London, 1663 and 1692). See also Barbosa Machado, *Bibl. Lusitana*; Fr. da Silva, *Dicionario bibliographico Portuguez*; Castelho, *Literaria Classica Portuguesa*.

PINTURICCHIO (1454-1513), whose full name was BERNARDINO DI BETTI, the son of a citizen of Perugia, Benedetto or Betto di Biagio, was one of a very important group of painters who inherited the artistic traditions and developed the style of the older Perugian painters such as Bonfigli and Fiorenzo di Lorenzo. According to Vasari he was a pupil of Perugino; and so in one sense no doubt he was, but rather as a paid assistant than as an apprentice. The strong similarity both in design and methods of execution which runs through the works of this later Perugian school, of which Perugino was the oldest member, is very striking; paintings by Perugino, Pinturicchio, Lo Spagna, and Raphael (in his first manner) may often be mistaken one for the other. In most cases, especially in the execution of large frescos, pupils and assistants had a large share in the work, either in enlarging the master's sketch to the full-sized cartoon, in transferring the cartoon to the wall, or in painting backgrounds, drapery, and other accessories. In this way the spirit and individuality of one man could impress itself indelibly on a numerous school of younger artists.

After assisting Perugino in the execution of his frescos in the Sistine Chapel, Pinturicchio was employed by various members of the Della Rovere family and others to decorate a whole series of chapels in the church of S. Maria del Popolo in Rome, where he appears to have worked from 1484, or earlier, to 1492 with little interruption. The earliest of these is an altarpiece of the Adoration of the Shepherds, in the first chapel (from the west) on the south, built by Cardinal Domenico della Rovere; a portrait of the cardinal is introduced as the foremost of the kneeling shepherds. In the lunettes under the vault Pinturicchio painted small scenes from the life of St Jerome. The frescos which he painted in the next chapel, that built by Card. Innocenzo Cibo, were destroyed in 1700, when the chapel was rebuilt by Card. Alderano Cibo. The third chapel on the south is that of Giov. della Rovere, duke of Sora, nephew of Sixtus IV., and brother of Giuliano, who was afterwards Pope Julius II.

This contains a fine altarpiece of the Madonna enthroned between Four Saints, and on the east side a very nobly composed fresco of the Assumption of the Virgin. The vault and its lunettes are richly decorated with small pictures of the life of the Virgin, surrounded by graceful arabesques; and the dado is covered with monochrome paintings of scenes from the lives of saints, medallions with prophets, and very graceful and powerfully drawn female figures in full length, in which the influence of Signorelli may be traced. In the fourth chapel Pinturicchio painted the Four Latin Doctors in the lunettes of the vault. Most of these frescos are considerably injured by damp, but happily have suffered little from restoration; the heads are painted with much minuteness of finish, and the whole of the pictures depend very largely for their effect on the final touchings *a secco*. The last paintings completed by Pinturicchio in this church were the frescos on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. In the centre is an octagonal panel of the Coronation of the Virgin, and round it medallions of the Four Evangelists—the spaces between them being filled up by reclining figures of the Four Sibyls. On each pendentive is a figure of one of the Four Doctors enthroned under a niched canopy. The bands which separate these pictures have elaborate arabesques on a gold ground, and the whole is painted with broad and effective touches, very telling when seen (as is necessarily the case) from a considerable distance below. No finer specimen of the decoration of a simple quadripartite vault can anywhere be seen.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. These rooms, called after their founder the *Appartamenti Borgia*, now form part of the Vatican library, and five of them still retain the fine series of frescos with which they were so skilfully decorated by Pinturicchio. The upper part of the walls and vaults, not only covered with painting, but further enriched with delicate stucco work in relief, are a masterpiece of decorative design applied according to the truest principles of mural ornament,—a much better model for imitation in that respect than the more celebrated Stanze of Raphael immediately over the Borgia rooms. The main subjects are—(1) the Annunciation, the Nativity, the Magi, and the Resurrection; (2) Scenes from the lives of St Catherine, St Antony, and other saints; (3) allegorical figures of Music, Arithmetic, and the like; (4) four figures in half length, with rich arabesques; (5) figures of the planets, the occupations of the various months, and other subjects. The sixth room was repainted by Perino del Vaga.¹

Though not without interruption, Pinturicchio, assisted by his pupils, worked in these rooms from 1492 till 1498, when they were completed. His other chief frescos in Rome, still existing in a very genuine state, are those in the Cappella Bufalini at the south-west of St Maria in Ara Coeli, probably executed from 1497 to 1500. These are well-designed compositions, noble in conception, and finished with much care and refinement. On the altar wall is a grand painting of St Bernardino of Siena between two other saints, crowned by angels; in the upper part is a figure of Christ in a vesica-glory, surrounded by angel musicians; on the left wall is a large fresco of the miracles done by the corpse of St Bernardino, very rich in colour, and full of very carefully painted heads, some being

¹ See Guattani, *Quadri nell' Appart. Borgia*, Rome, 1820.

portraits of members of the Bufalini family, for whom these frescos were executed. One group of three females, the central figure with a child at her breast, is of especial beauty, recalling the grace of Raphael's second manner. The composition of the main group round the saint's corpse appears to have been suggested by Giotto's painting of St Francis on his bier in S. Croce at Florence. On the vault are four noble figures of the Evangelists, usually attributed to Luca Signorelli, but certainly, like the rest of the frescos in this chapel, by the hand of Pinturicchio. On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists, a work which still exists in a fair state of preservation and unrestored. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed. For these he received fifty gold ducats.

Among his panel pictures the following are the most important. An altarpiece for St Maria de' Fossi at Perugia, painted in 1496-98, now moved to the picture gallery, is a Madonna enthroned among Saints, graceful and sweet in expression, and very minutely painted; the wings of the retable have standing figures of St Augustine and St Jerome; and the *predella* has paintings in miniature of the Annunciation and the Evangelists. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The angels at the sides in beauty of face and expression recall the manner of Lorenzo di Credi or Da Vinci. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several well-executed portraits occur among the kneeling saints. The Virgin, who kneels at Christ's feet to receive her crown, is a figure of great tenderness and beauty, and the lower group is composed with great skill and grace in arrangement. Other important panel paintings by Pinturicchio exist in the cathedral of Spello, in the Siena gallery, at Florence, at Perugia, and in other collections.

In 1501 Pinturicchio painted several fine frescos in S. Maria Maggiore at Spello,—all very decorative, and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinvs Pintvrichivs Pervsinvs." They are much injured by damp and clumsy restoration. The most striking of all Pinturicchio's frescos, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1495 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Æneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract, given in full by Milanese (Vasari, iii. p. 519), is a very interesting one; it specially provides that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. In fact when closely examined the evidence which would give Raphael an important share in the execution of these fine paintings amounts to very little. The document provides for the price of these frescos, namely one thousand gold ducats, to be paid in various instalments. The work was begun early in 1503, but was interrupted for a while by the death of Pius III. His will, however, provided for the completion of the work by his executors, and the whole series were finished in 1507. The subjects are (1) the journey of the young Sylvius Piccolomini to the council of Basel, in the suite of Cardinal Capranica; (2) his reception by James I. of Scotland as envoy from the council of Basel; (3) his being crowned with the poet's laurel by Frederick III.; (4) his reception by Pope Eugenius IV. as ambassador from Frederick III.; (5) outside the wall of Siena he presents to

Frederick III. his bride Leonora, infanta of Portugal; (6) he receives the cardinal's hat from Pope Calixtus III.; (7) he is borne in procession after his election as Pope Pius II.; (8) he presides at a council at Mantua; (9) he canonizes St Catherine of Siena; (10) he arrives in Ancona to promote the crusade against the Turks. In addition to these there is, outside the library, over the door, the Coronation of Pius III.

Though this splendid series of paintings are laid in with true fresco-colours, there is but little *fresco buono* visible; almost the whole is painted over *a secco* with colours much more brilliant in tone than could be used on the wet stucco. This retouching, which was employed by all fresco painters, was used by Pinturicchio more than by most artists. In the lower part of the scene of St Catherine's canonization he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael. The paintings are all finished with much care, but Pinturicchio has not kept to the flat and simply decorative treatment of his earlier manner; there is much more of aerial perspective and distance destroying the apparent solidity of the wall surface.

In 1508 Pinturicchio painted another panel of the Madonna enthroned among Saints for the church of the Minori Conventuali at Spello. It is now over the altar in the sacristy. On his return to Siena he painted a whole series of frescos on the walls of the Palazzo Petrucci, now all destroyed except one scene of the return of Ulysses to Penelope (or possibly Collatinus and Lucretia), which is now in the National Gallery of London, transferred to canvas. One of his last works, painted in 1513, the year of his death, is a very beautiful and highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. Pinturicchio married Grania di Niccolò, and had by her two sons and four daughters; there is probably no truth in the story of his being starved by his wife during his last illness.

The frescos in the Cappella Bufalini were engraved in ten plates by Fran. Giangiacomo, and published by the Calcografia Camerale of Rome. The Siena library series were engraved by Faucci in the last century, and more recently by Lasinio. Neither set is remarkable for fidelity or spirit. The Siena frescos and those at Spello have been published in chromo-lithograph by the Arundel Society of London.

Pinturicchio's worth as a painter has been for the most part undervalued, partly owing to the very strong prejudice and dislike which tinges Vasari's biography of him. Even recent writers, such as Crowe and Cavalcaselle, have hardly done him justice. A fairer estimate of his position in the history of art is given by Vermiglioli, *Memorie di Pinturicchio*, Perugia, 1837; and in the valuable notes and appendix of Milanese's edition of Vasari, iii. p. 493-531, Florence, 1878. See also Schmarow, *Raphael und Pinturicchio in Siena*, Stuttgart, 1880, and *Pinturicchio in Rom*, Stuttgart, 1882, both well illustrated by photolithography. (J. H. M.)

PINZON, a family of wealthy Spanish navigators, of Palos de Moguer, in Andalusia, three members of which—Alonso, Francesco, and Vicente, brothers—were associated with Columbus in his great discovery.

MARTIN ALONZO PINZON, born about the middle of the 15th century, gave material assistance to Columbus in carrying out his project. In the expedition of 1492 Alonzo commanded the "Pinta," on board of which his brother Francesco was pilot; another brother, Vicente Yañez, had command of the "Nina." It was at Alonzo's persuasion that on October 7th the course of the expedition was changed to the south-west; the island of Guanahani or San Salvador, four days after, was sighted. On November 21, off the coast of Cuba, Alonzo separated himself from the expedition, and crowded sail to the westward, hoping to be the first to arrive at the land of gold of which they had heard the natives speak. After an absence of six weeks he rejoined Columbus, who accepted the excuses he gave for his absence. On the return journey Alonzo again separated from his leader, probably by design, and when Columbus arrived at Palos on March 15, 1493, he learned that Alonzo had already landed at Bayona in Galicia. If his object was to forestall Columbus and obtain the credit of being the discoverer of the New World, his intentions were foiled; he was refused the

audience which he craved of the sovereigns, and very shortly after died, it is supposed of chagrin. Even although it could be proved that Alonzo's intentions were dishonourable, we should remember that it was largely through his liberality that Columbus was enabled to carry out his immortal voyage.

VICENTE YAÑEZ PINZON, who commanded the "Nina," also gave Columbus material help, and remained loyal to his leader throughout. In after years he made important discoveries on his own account. In 1499 he sailed with four caravels across the Atlantic to the south-west, and on January 20, 1500, he struck the South-American continent at Cape S. Agostinho, its most easterly projection, three months before the Portuguese navigator Cabral reached Brazil, the discovery of which is generally attributed to him. Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, and went as far at least as what is now Costa Rica. After touching at Hayti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in the end of September 1500. Although concessions were made to him, and he was created governor of the newly discovered lands by Ferdinand and Isabella, he does not seem to have ever taken possession. In 1508 we find Vicente sailing with Juan Diaz de Solis along the east coast of South America, in their attempt to find an opening towards the west that would conduct them to the Spice Islands. He did not get beyond the 40th degree of S. lat., about the mouth of the Rio Negro, having passed the mouth of the La Plata without recognizing it. After 1523 all traces of Vicente are lost.

PIOMBO, SEBASTIANO DEL. See SEBASTIANO.

PIOTRKÓW, the chief town of a government of the same name in Russian Poland, and formerly the seat of the high court of Poland, is situated on the railway from Warsaw to Vienna, 90 miles by rail to the south-west of the capital, 5 miles to the west of the river Pilica. Ten years ago it was a poor town of 17,000 inhabitants, but it has grown during the last few years, partly as the seat of the provincial administration, and partly in consequence of the development of trade. In April 1882 it had 23,050 inhabitants, including 3000 military. Its manufactures are still insignificant; it has a few flour-mills, saw-mills, soap-works, and breweries.

PIOZZI, HESTER LYNCH (1741-1821), the daughter of John Salisbury of Bodville, Carnarvonshire, was born there, as it would appear from a protracted dispute between Croker and Macaulay, 27th January 1741. After an education which extended considerably beyond that given to most ladies of her period—for she was acquainted with the learned languages as well as with French, Italian, and Spanish—she was married in 1763 to Henry Thrale, a brewer of Southwark, whose house was at Streatham on the south-east corner of Tooting Beck Common. In this retreat she drew around her many of the most distinguished men of letters of the age. She was introduced to Johnson by Arthur Murphy in the year after her marriage, and for nearly twenty years the sage remained on the closest intimacy with her. He travelled with them in Wales in 1774, and visited France in their company in 1775. Boswell's first visit to Streatham took place in October 1769. Madame D'Arblay was first received there in August 1778. In spite of this intercourse with the principal writers of the day troubles grew upon her in her married life. Her talents were not appreciated by her husband; he was always ill and frequently in pecuniary

anxiety; and when children were born to her they often succumbed to sickness. After some years' illness Mr Thrale died on April 4, 1781, and, as the brewery in the borough sold for £135,000, the widow found herself amply provided for. At the time of Mr Thrale's death Dr Johnson was in declining health, and he soon began to think himself slighted, nor was his indignation abated at the announcement in the spring of 1783 of her engagement to Piozzi, an Italian musician. For a time the engagement was broken off, but it was quickly resumed, and on the 25th of July 1784 they were married. The union provoked the resentment of her children, and the undying denunciations of Dr Johnson; but, when her husband was found to be a man of quiet and inoffensive manners and a careful guardian of his wife's resources, her children acquiesced in the marriage and most of her friends returned to her. Baretti, always her enemy, abused her, and Boswell ridiculed her, but her character has survived the insinuations of the one and the open malevolence of the other, as well as the satiric attacks of Peter Pindar. Piozzi died of gout at Brynbellia, March 1809, and from that time his widow's life was chiefly spent in the social circles of Bath and Clifton or in the retirement of Penzance. When long past seventy she took a fancy to William Augustus Conway the actor, and the "love letters" which she wrote to him have been published with a catchpenny title. She died at Clifton, 2d May 1821.

Mrs Piozzi was bright and witty, and possessed of manners which, if not refined, never failed to attract. Several of her literary publications have long since perished from want of vitality, but her little poem of "The Three Warnings" forms a part of most selections of English poetry. Her *Anecdotes of Dr Johnson*, now a scarce book, are contained, "as she herself gave them to the world," in the concluding volume of Napier's *Johnson* (1884), and her notes to Wraxall's *Historical Memoirs* are reprinted in the 1884 edition of that work. The *Anecdotes* and the *Letters to and from Dr Johnson* are inferior in interest only to the work of Boswell. Two editions of the *Autobiography* of Mrs Piozzi, under the editorship of Abraham Hayward, have been issued, and the Rev. Edward Mangin published in 1833, under the disguise of "by a friend," a thin volume of *Piozziana*. Her features are reproduced in the lady's countenance in Hogarth's picture of the Lady's Last Stake.

PIPE (see MUSIC, vol. xvii. p. 77; and ORGAN, *ib.* p. 829). Strutt, in his *Sports and Pastimes of the People of England*, gives representations of the pipe and tabor as used in England in the 14th century to accompany a dancing-dog, a cock on stilts, a horse rearing, &c. From the drawings we cannot ascertain the nature of the pipe represented. We may, however, suppose it to have been similar to the *galoubet* used in France, along with the tabor, from a very remote period. This *galoubet* is a small instrument of the flageolet kind. Its use for more than the last two centuries has been confined to Provence. It has only three finger-holes, and is played with the left hand, whilst the right beats the tabor, which is attached to the performer. The compass of the *galoubet* is two octaves and a tone from D on the third line of the treble clef up to E in *altissimo*. Great skill is required to bring out all the sounds of its compass. Some of the players on this small and imperfect instrument are said to be so dexterous as to be able to perform upon it very difficult pieces of music composed for other instruments, such as the violin, &c. It is always accompanied by the tabor, which is a small drum of a cylindrical form, and rather longer and narrower in its relative proportions than the common drum. In the last century several books of instruction were published at Paris by distinguished performers on the *galoubet*.

PIPE, TOBACCO. The smoking of tobacco in pipes is a custom which prevailed in America for a period of unknown duration previous to the discovery of that con-

continent by Columbus. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in the States of Ohio, Indiana, Illinois, and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type. The pipe, cut out of a single piece of stone, consists of a slightly convex platform or base, generally from 3 to 4 inches in length, and about an inch broad, with the bowl on the centre. A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked. In the

commonest forms the bowl is a simple cylinder or urn (fig. 1), but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles, and human heads, often grotesque and fantastic, but always vigorously expressed (fig. 2). These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mis-

FIG. 1.—"Monitor" Pipe.

FIG. 2.—Heron Pipe.

issippi valley. The wide area over which they, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, &c., are elaborately moulded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connexion with the superstitious rites and usages of the race. The calumet, peace pipe, or medicine pipe is an object of the most profound veneration, entrusted to the care of a highly honoured official, and produced and smoked with much ceremony only on occasions of great importance and solemnity. It is remarkable that, whilst the most ancient American pipes had no separate stem, it is the stem only of the medicine pipe which is the object of veneration among the Indians, the bowl used being a matter of indifference. The favourite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained easily-worked stone of a rich red colour of the Côteau des Prairies, west of the Big Stone Lake in Dakota. The quarries were formerly neutral ground among the warring Indian tribes, many sacred traditions being associated with the locality and its product (see Longfellow's *Hiawatha*, i.). The Babeen Indians of the British-Columbian coast carve from a soft blue clay slate very elaborate and massive pipes with intricate pierced work and fantastic animal forms, the pipe tube being pierced from some protruding part of the sculpture.

There is considerable dispute as to whether pipes for smoking were at all known in Europe previous to the discovery of America. That tobacco-smoking was unknown is certain; but pipes of iron, bronze, and clay have been so frequently found associated with Roman remains and other antiquities as to lead many authorities to maintain that such pipes must have been anciently used for burning incense or for smoking aromatic herbs or hemp. Throughout Great Britain and Ireland small clay pipes are fre-

quently dug up, in some instances associated with Roman relics. These are known amongst the people as elfin, fairy, or Celtic pipes, and in some districts supernatural agencies have been called in to account for their existence. The elfin pipes have commonly flat broad heels in place of the sharp spur now found on clay pipes, and on that flat space the mark or initials of the maker is occasionally found. There is no reason to believe that these pipes are older than the 17th century. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use the implement. The pipe makers of London became an incorporated body in 1619, and from England the other nations of Europe learned the art of making clay pipes. Baillard, in his *Discours du Tabac* (1668) says of the English—"Ces derniers ont inventé les pipes de terre cuite, qui ont cours aujourd'hui par tout le monde."

The habit of smoking with pipes spread with incredible rapidity; and among the various peoples the pipe assumed special characteristics, and its modifications became the medium of conveying social, political, and personal allusions, in many cases with no little artistic skill and humour. The pipe also became the object of much inventive ingenuity, and it varied as greatly in material as in form—wood, horn, bone, ivory, stone, precious and other metals, amber, glass, porcelain, and above all clay being the materials employed in various forms. By degrees pipes of special form and material came to be associated with particular people, so that now we have the elongated painted porcelain bowls and pendulous stem of the German peasantry, the red clay bowl and long cherry wood stem of the Turk, and the very small metallic bowl and cane stem of the Japanese, &c. The most luxurious and elaborate form of pipe is the Persian *kalyan*, hookah, or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base, and the snake or long flexible tube ending in the mouthpiece. The tobacco, which must be previously prepared by steeping in water, is placed in the head and lighted with live charcoal, a wooden stem passes from its bottom down into the water which fills the base, and the tube is fitted to a stem which ends in the bottle above the water. Thus the smoke is cooled and washed before it reaches the smoker by passing through the water in the bottle, and by being drawn through the coil of tube frequently some yards in length. The bottles are in many cases made of carved and otherwise ornamented cocoa-nut shells, whence the apparatus is called *nārgila*, from *nārgil*, a cocoa-nut. Silver, gold, damascened steel, and precious stones are freely used in the making and decoration of these pipes for wealthy smokers.

Pipe Manufacture.—The regular pipe-making industries divide into many branches, of which the more important are the clay pipe, meerschaum (real and artificial), and wooden bowl trades. Clay pipes are made in prodigious numbers by hand labour with an iron mould and a steel wire for forming the tube of the stem. Pipe moulding is a very simple operation in pottery, and the work is performed with astonishing celerity. A number of machines have been devised for automatic pipe-moulding; but the manual operations are so rapid and inexpensive that there is little margin for saving by the substitution of machinery. The pipes are very lightly fired so as to keep them soft and porous; and so cheaply made are they that the commoner kinds can be retailed at a profit for a farthing each. The principal centre of the clay pipe industry is at Broseley in Staffordshire, where the trade has been established since the early part of the 17th century. Meerschaum pipes (see MEERSCHAUM, vol. xv. p. 825) are the expensive luxury of the European smoker, and large sums of money are occasionally expended on the artistic treatment of the meerschaum bowl or on the adornment of its adjuncts. The common meerschaum is generally provided with a mouth-piece of amber, but modern ingenuity has succeeded in providing a remarkably clever imitation of both substances, so that a large proportion of the so-called meerschaum pipes are factitious. The headquarters of the meerschaum pipe

industry is at Ruhla in Thuringia, and in connexion with an official inquiry into the German tobacco trade in 1879 the average production of pipes and pipe adjuncts in that district for several years was ascertained. Of pipe bowls there were made yearly 540,000 genuine meerschaums; 5,400,000 artificial meerschaums; 4,300,000 wooden heads; 9,600,000 common porcelain bowls (the favourite of the German peasant); and 2,700,000 fine clay or lava bowls. Further the trade included 15,000,000 pipe stems or tubes of various materials; 19,200,000 adjuncts, such as flexible tubes, chains, tops, &c.; 144,000 pipe cases; 9,600,000 mouth-pieces and cigar-holders of amber, horn, meerschaum, wood, &c.; and finally 15,000,000 complete pipes of various materials. The whole annual value of the industry is estimated at £1,000,000 sterling. The favourite wooden pipe generally known as a briar-wood or briar-root pipe is really made from the roots of the tree heath, *Erica arborea* (French, *bruyère*), principally obtained on the hills of the Maremma and taken thence to Leghorn. There the roots are shaped into blocks each suitable for a pipe, the cutting of the wood so as to avoid waste requiring considerable skill. These blocks are simmered in a vat for twelve hours, which gives them the much appreciated yellowish-brown hue of a good "briar-root." So prepared the blocks are exported for boring and finishing to St Claude (Jura) in France and to Nuremberg, the two rival centres of the wooden pipe trade. (J. P.A.)

PIPE-FISHES, small marine fishes, which with the Sea-horses form a distinct family, *Syngnathidae*, of the order of Lophobranchiate Fishes (see ICHTHYOLOGY, vol. xii. p. 694). The name is derived from the peculiar form of their

FIG. 1.—*Syngnathus acus*, male, with sub-caudal pouch.

snout, which is produced into a more or less long tube, ending in a narrow and small mouth which opens upwards and is toothless. The body and tail are long and thin, snake-like, encased in hard integuments which are divided into regularly arranged segments. This dermal skeleton shows several longitudinal ridges, so that a vertical section through the body represents an angular figure, not round or oval as in the majority of other fishes. A dorsal fin is always present, and the principal (in some species, the only) organ of locomotion. The ventral fins are as constantly absent, and the other fins may or may not be developed. The gill-openings are extremely small, and placed near the upper posterior angle of the gill-cover. Pipe-fishes are abundant on such coasts of the tropical and temperate zones as offer by their vegetation shelter to these defenceless creatures. They are very bad swimmers, slowly moving through the water by means of the rapid undulatory movement of the dorsal fin. Their tail, even when provided with a caudal fin, is of no use in swimming, and not prehensile as in sea-horses. Specimens, therefore, are not rarely found at a great distance from land, having been resistlessly carried by currents into the open ocean; one species, *Syngnathus pelagicus*, has an extraordinarily wide range over the tropical seas, and is one of the common fishes inhabiting the vegetation of the Sargasso Sea. In pipe-fishes the male is provided with a pouch—in some species on the abdomen, in others on the lower side of the tail—

FIG. 2.—Sub-caudal pouch of *Syngnathus acus*, with the young ready to leave the pouch. One side of the membrane of the pouch is pushed aside to admit of a view of its interior. (Natural size.)

in which the ova are lodged during their development. This marsupial pouch is formed by a fold of the skin developed from each side of the trunk or tail, the free margins of the fold being firmly united in the median line throughout the period during which the eggs are being hatched. When the young are hatched the folds separate, leaving a wide slit, by which the young gradually escape when quite able to take care of themselves. Nearly a hundred different species of pipe-fishes are known, of which *Siphonostoma typhle*, *Syngnathus acus* (the Great Pipe-fish, up to 18 inches in length), *Nerophis æquoreus* (Ocean Pipe-fish), *Nerophis ophidion* (Straightnosed Pipe-fish), and *Nerophis lumbriciformis* (Little Pipe-fish) are British species. The last three are destitute of a caudal fin.

PIPIT, French *Pipit*, cognate with the Latin *Pipio* (see PIGEON, *supra* p. 84), the name applied by ornithologists to a group of birds having a great resemblance both in habits and appearance to the LARKS (vol. xiv. p. 317), with which they were formerly confounded by systematists as they are at the present day in popular speech, but differing from them in several important characters, and, having been first separated to form the genus *Anthus*, which has since been much broken up, are now generally associated with the WAGTAILS (*q.v.*) in the Family *Motacillidae*.¹ Pipits, of which over fifty species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguei*, the Prairie-Lark of the north-western plains, and *Anthus ludovicianus*, the American Titlark, which last is very nearly allied to the so-called Water-Pipit of Europe, *A. spiolella*. To most English readers the best known species of Pipit is the Titlark or Meadow-Pipit, *A. pratensis*, a bird too common to need description, and abundant on pastures, moors, and uncultivated districts generally; but in some localities the Tree-Pipit, *A. trivialis*, or *A. arboreus* of some authors, takes its place, and where it does so it usually attracts attention by its loud song, which is not unlike that of a Canary-bird, but delivered (as appears to be the habit of all the Pipits) on the wing and during a short circuitous flight. Another species, the Rock-Lark, *A. obscurus*, scarcely ever leaves the sea-coast and is found almost all round the British Islands. The South-African genus *Macronyx*, remarkable for the extreme length of its hind claw, is generally placed among the Pipits, but differs from all the rest in its brighter coloration, which has a curious resemblance to the American genus *Sturnella* (see ICTERUS, vol. xii. p. 697), though the bird is certainly not allied thereto. (A. N.)

PIPPI, GIULIO (c. 1492–1546), the head of the Roman school of painting in succession to Raphael. This prolific painter, modeller, architect, and engineer is currently named GIULIO (or JULIO) ROMANO, from the place of his birth—Rome, in the Macello de' Corbi. His name in full was Giulio di Pietro di Filippo de' Giannuzzi,—Giannuzzi being the true family name, and Pippi (which has practically superseded Giannuzzi) being an abbreviation from the name of his grandfather Filippo.

The date of Giulio's birth is a little uncertain. Vasari (who knew him personally) speaks of him as fifty-four years old at the date of his death, 1st November 1546; thus he would have been born in 1492. Other accounts assign 1498 as the date of birth. This would make Giulio young indeed in the early and in such case most precocious stages of his artistic career, and would show him as dying, after an infinity of hard work, at the comparatively early age of forty-eight.

Giulio must at all events have been quite youthful

¹ Pipits can always be distinguished from Larks by having the hind part of the "tarsus" undivided, while the Larks have it scutellated.

when he first became the pupil of Raphael, and at Raphael's death in 1520 he was at the utmost twenty-eight years of age. Raphael had loved him as a son, and had employed him in some leading works, especially in the Loggie of the Vatican; the series there popularly termed "Raphael's Bible" is done in large measure by Giulio,—as for instance the subjects of the Creation of Adam and Eve, Noah's Ark, and Moses in the Bulrushes. In the saloon of the "Incendio del Borgo," also, the figures of Benefactors of the Church (Charlemagne, &c.) are Giulio's handiwork. It would appear that in subjects of this kind Raphael simply furnished the design, and committed the execution of it to some assistant, such as Giulio,—taking heed, however, to bring it up, by final retouching, to his own standard of style and type. Giulio at a later date followed out exactly the same plan; so that in both instances inferiorities of method, in the general blocking-out and even in the details of the work, are not to be precisely charged upon the *caposcuola*. Amid the multitude of Raphael's pupils, Giulio was eminent in pursuing his style, and showed universal aptitude; he did, among other things, a large amount of architectural planning for his chief. Raphael bequeathed to Giulio, and to his fellow-pupil Gianfrancesco Penni ("Il Fattore"), his implements and works of art; and upon them it devolved to bring to completion the vast fresco-work of the "Hall of Constantine" in the Vatican—consisting, along with much minor matter, of the four large subjects, the Battle of Constantine, the Apparition of the Cross, the Baptism of Constantine, and the Donation of Rome to the Pope. The two former compositions were executed by Pippi, the two latter by Penni. The whole of this onerous undertaking was completed within a period of only three years,—which is the more remarkable as, during some part of the interval since Raphael's decease, the Fleming, Adrian VI., had been pope, and his anti-aesthetic pontificate had left art and artists almost in a state of inanition. Clement VII. had now, however, succeeded to the papedom. By this time Giulio was regarded as the first painter in Rome; but his Roman career was fated to have no further sequel.

Towards the end of 1524 his friend the celebrated writer Baldassar Castiglione seconded with success the urgent request of the duke of Mantua, Federigo Gonzaga, that Giulio should migrate to that city, and enter the duke's service for the purpose of carrying out his projects in architecture and pictorial decoration. These projects were already considerable, and under Giulio's management they became far more extensive still. The duke treated his painter munificently as to house, table, horses, and whatever was in request; and soon a very cordial attachment sprang up between them. In Pippi's multifarious work in Mantua three principal undertakings should be noted. (1) In the Castello he painted the History of Troy, along with other subjects. (2) In the suburban ducal residence named the Palazzo del T (this designation being apparently derived from the form of the roads which led towards the edifice) he rapidly carried out a rebuilding on a vastly enlarged scale,—the materials being brick and terra-cotta, as there is no local stone,—and decorated the rooms with his most celebrated works in oil and fresco painting—the story of Psyche, Icarus, the Fall of the Titans, and the portraits of the ducal horses and hounds. The foreground figures of Titans are from 12 to 14 feet high; the room, even in its structural details, is made to subserve the general artistic purpose, and many of its architectural features are distorted accordingly. Greatly admired though these pre-eminent works have always been, and at most times even more than can now be fully ratified, they have suffered severely at the hands of restorers, and modern eyes see

them only through a dull and deadening fog of renovation. The whole of the work on the Palazzo del T, which is of the Doric order of architecture, occupied about five years. (3) Pippi recast and almost rebuilt the cathedral of Mantua; erected his own mansion, replete with numerous antiques and other articles of vertu; reconstructed the street architecture to a very large extent, and made the city, sapped as it is by the shallows of the Mincio, comparatively healthy; and at Marmiruolo, some five miles distant from Mantua, he worked out other important buildings and paintings. He was in fact, for nearly a quarter of a century, a sort of Demiurgus of the arts of design in the Mantuan territory.

Giulio's activity was interrupted but not terminated by the death of Duke Federigo. The duke's brother, a cardinal who became regent, retained him in full employment. For a while he went to Bologna, and constructed the façade of the church of S. Petronio in that city. He was afterwards invited to succeed Antonio Sangallo as architect of St Peter's in Rome,—a splendid appointment, which, notwithstanding the strenuous opposition of his wife and of the cardinal regent, he had almost resolved to accept, when a fever overtook him, and, acting upon a constitution somewhat enfeebled by worry and labour, carried him off on 1st November 1546. He lies buried in the church of S. Barnaba in Mantua. At the time of his death Giulio enjoyed an annual income of more than 1000 ducats, accruing from the liberalities of his patrons. He left a widow, and a son and daughter. The son, named Raffaello, studied painting, but died before he could produce any work of importance; the daughter, Virginia, married Ercole Malatesta.

Wide and solid knowledge of design, combined with a promptitude of composition that was never at fault, formed the chief motive power and merit of Giulio Romano's art. Whatever was wanted, he produced it at once, throwing off, as Vasari says, a large design in an hour; and he may in that sense, though not equally so when an imaginative or ideal test is applied, be called a great inventor. It would be difficult to name any other artist who, working as an architect, and as the plastic and pictorial embellisher of his architecture, produced a total of work so fully and homogeneously his own; hence he has been named "the prince of decorators." He had great knowledge of the human frame, and represented it with force and truth, though sometimes with an excess of movement; he was also learned in other matters, especially in medals, and in the plans of ancient buildings. In design he was more strong and emphatic than graceful, and worked a great deal from his accumulated stores of knowledge, without consulting nature direct. As a general rule, his designs are finer and freer than his paintings, whether in fresco or in oil—his easel pictures being comparatively few, and some of them the reverse of decent; his colouring is marked by an excess of blackish and heavy tints.

Giulio Romano introduced the style of Raphael into Mantua, and established there a considerable school of art, which surpassed in development that of his predecessor Mantegna, and almost rivalled that of Rome. Very many engravings—more than three hundred are mentioned—were made contemporaneously from his works; and this not only in Italy, but in France and Flanders as well. His plan of entrusting principally to assistants the pictorial execution of his cartoons has already been referred to; Primaticcio was one of the leading coadjutors. Rinaldo Mantovano, a man of great ability who died young, was the chief executant of the Fall of the Giants; he also co-operated with Benedetto Pagni da Pescia in painting the remarkable series of horses and hounds, and the story of Psyche. Another pupil was Fermo Guisoni, who remained settled in Mantua. The oil pictures of Giulio Romano are not generally of high importance; two leading ones are the Martyrdom of Stephen, in the church of that saint in Genoa, and a Holy Family in the Dresden Gallery. Among his architectural works not already mentioned is the Villa Madama in Rome, with a fresco of Polyphemus, and boys and satyrs; the Ionic façade of this building may have been sketched out by Raphael.

Vasari gives a pleasing impression of the character of Giulio. He was very loving to his friends, genial, affable, well-bred, temperate in the pleasures of the table, but liking fine apparel and a handsome scale of living. He was good-looking, of middle height, with black curly hair and dark eyes, and an ample beard; his portrait, painted by himself, is in the Louvre. (W. M. R.)

PIPPIN, or PEPIN, a name borne by several members of the Carolingian family. (1) Pippin of Landen, or Pippin the Old, mayor of the palace, died 639. (2) His grandson, Pippin of Heristal, the father of Charles Martel, died 714. (3) Martel's son, Pippin the Short, king of the Franks, died 768. See, for these three, FRANCE, vol. ix. p. 530 sq. (4) Pippin, son of Charles the Great (776–810), was his father's deputy in Italy, and as such was anointed "king for Italy" by Pope Adrian I. in 781. (5) Pippin, second son of Louis the Pious, appointed king of Aquitaine by his father in 817, died in 838 after a reign spent in the family conflicts of the period. (6) The son of the last-named Pippin was called to the throne by the Aquitanians on his father's death, and maintained himself with varying fortunes against Charles the Bald, to whom Louis had given the vacant throne, till in 864 he was taken by treachery and soon died in confinement.

PIQUA, a city of Miami county, Ohio, U.S., is situated in a rich agricultural district on the Miami river, on the Miami and Erie Canal, and on the Pittsburgh, Cincinnati, and St Louis and the Cincinnati and Michigan railways, about 90 miles N. by E. of Cincinnati. Besides a large agricultural trade the city has woollen manufactures, iron foundries, and agricultural machine works. The population, 3277 in 1850, was 5967 in 1870 and 6131 in 1880.

PIQUET, a game at cards. The name, of uncertain etymology, is probably from *pique* (the spade suit). The Germans had formerly a *Schwerter* game, the packs used being like piquet packs. The *pique* of French cards corresponds to the *spade* (sword) of Italian and to the *espadas* of Spanish cards. Hence *piquet* may be the *sword game*.

It seems likely that piquet is a development of *ronfa*, a game mentioned by Berni in 1526; *la ronfle* (included in Rabelais's list, circa 1530) may be regarded as the same game. The point at piquet was anciently called *ronfle*.

The Spanish name of the game was *cientos* (centum, a hundred). Piquet was played in England under the name of *cent*, or *sant*, probably as early as 1550 (contemporaneously with the marriage of Mary to Philip of Spain). About the middle of the 17th century (shortly after the marriage of Charles I. to Maria Henrietta of France) the name *cent* was dropped in England, and the French equivalent, *piquet*, adopted.

Piquet is played by two persons, with a pack of thirty-two cards,—the sixes, fives, fours, threes, and twos being thrown out from a complete pack. Until recently the *partie* was the best of five games of a hundred up (a player not obtaining fifty losing a double game). But now the *partie* is generally determined in six hands, the player making the largest aggregate score being the winner. The number of points won is the difference between the two scores, with a hundred added for the game. If, however, the loser fails to make a hundred in six hands, the number of points won is the two scores added together, with a hundred for the game. Piquet played in this way is called *Rubicon Piquet*.

The dealer (see "Laws") deals twelve cards to his adversary and twelve to himself, by two at a time or by three at a time to each alternately. He then places the undealt cards, called the *stock*, face downwards on the table.

The players now look at their hands and *discard*, i.e., put out, such cards as they deem advisable, and take in an equivalent number from the stock. The elder hand (non-dealer) may exchange five or any less number. He separates his discard from his hand, places it face downwards on the table, and takes from the top of the stock the number discarded. If he discards less than five, he must state how many he leaves. He is entitled to look at cards he leaves, replacing them face downwards on the top of the stock.

The younger hand may exchange three cards or any less number. If the elder hand leaves any cards, the younger may exchange as many as remain in the stock, discarding an equal number. He takes his cards from the top of the stock, including any left by the elder hand. If the younger hand leaves any cards, he announces

the number left. He has the option of looking at cards he leaves. If he looks at them, he must show them to the elder hand, after the elder has named the suit he will first lead, or has led a card. If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before he plays to the card first led, or, if so required, after the dealer has named the suit he will first lead.

Each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next *calls* his point, sequences, and quatorzes or trios, and, if *good*, scores for them.

The *point* must be called first or the right to call a point is lost. It is scored by the player who announces the suit of greatest strength, valued thus: ace, 11; court cards, 10 each; other cards, the number of pips on each. Thus, if the elder hand's best suit is ace, king, knave, nine, eight, he calls "five cards." If the younger hand has no suit of five cards, he says "good." The elder hand then says "in spades," or whatever the suit may be, or shows his point face upwards. If the younger hand has a suit of more than five cards, he says "not good." If the younger hand has also five cards, he says "equal" or "what do they make?" when the elder calls "forty eight" (or "making eight," short for forty-eight). The younger must not inquire what the point makes unless he has an equal number of cards. If the younger hand's five cards make less than forty-eight he says "good"; if exactly forty-eight, he says "equal"; if more than forty-eight, he says "not good."

The player whose point is good reckons one for each card of it; if the points are equal neither player scores for point.

Sequences are usually called next, the elder hand stating what his best sequence is, and the younger saying, "good," "equal," or "not good," as in the case of the point. Any three or more consecutive cards of the same suit held in hand constitute a sequence. The order of the cards is as follows:—ace (highest), king, queen, knave, ten, nine, eight, seven (lowest). A sequence of three cards is called a *tierce*; of four, a *quart*; of five, a *quint*; of six, a *sixième*; of seven, a *septième*; of eight, a *huitième*. A tierce of ace, king, queen is called a *tierce major*; a tierce of king, queen, knave is called *tierce to a king* (and so on for other intermediate sequences according to the card which heads them); a tierce of nine, eight, seven is called a *tierce minor*. Sequences of four or more cards follow the same nomenclature, e.g., ace, king, queen, knave is a *quart major*; knave, ten, nine, eight is a *quart to a knave*; and so on.

A sequence of a greater number of cards is good against a sequence of a smaller number; thus, a *quart minor* is good against a *tierce major*. As between sequences containing the same number of cards, the one headed by the highest card is good; thus, a *quart to a queen* is good against a *quart to a knave*. Only identical sequences can be equal.

The elder hand announces, say, a *quint major*. If the younger has a *sixième* he says "not good"; if he has a *quint major* he says "equal"; if he has a lower sequence, or no sequence, he says "good." The player whose sequence is good reckons one for each card of it, and ten in addition for quints or higher sequences. Thus a *tierce* counts three; a *quart*, four; a *quint*, fifteen (5+10); a *sixième*, sixteen; and so on. If the elder hand's sequence is good, he names the suit, or shows it face upwards.

If the highest sequence (or the sequence first called) is good, all lower sequences can be reckoned, notwithstanding that the adversary has a sequence of intermediate value. For example, A has a *quart to a queen* (good), and a *tierce minor*. He calls and reckons seven, notwithstanding that B has a *quart to a knave*. B's *quart* counts nothing.

If the highest sequence is equal, neither player scores anything for sequence, even though one player may hold a second sequence of equal or inferior value.

Quatorzes are composed of four aces, four kings, four queens, four knaves, or four tens; *trios* of three of any of these. They are called and reckoned as before, except that here there can be no equality. A *quatorze*, if good, reckons fourteen; a *trio*, if good, reckons three. Any *quatorze* is good against a *trio*; if each player has a *quatorze* the highest is good; the same if each has a *trio*. As in the case of sequences, anything that is good enables the player to reckon all smaller *quatorzes* or *trios* in his hand. A *quatorze* or *trio* is called thus:—the elder hand says "four aces," "three queens," or as the case may be; the younger replies "good" or "not good," as before. When a player calls a *trio* of a denomination of which he might hold a *quatorze*, the adversary is entitled to be informed which card is not reckoned. Thus, A, who might hold four kings, calls "three kings"; B says "good"; A says "I do not reckon the king of diamonds," or whichever king it may be that he has put out or suppresses.

When the elder hand has done calling, he leads a card. Before playing to this card, the younger hand reckons all that he has good, stating of what cards his claims are composed, or showing the cards claimed for.

The next step is *playing* the hands. The elder hand leads any

card he pleases; the younger plays to it. The younger hand must follow suit if able; otherwise he may play any card he thinks fit. The two cards thus played constitute a *trick*. The trick is won by the higher card of the suit led. It is not compulsory to win the trick if able to follow suit without. The winner of the trick leads to the next, and so on until the twelve cards in hand are played out.

During the play of the hands the leader counts one for each card led, whether it wins the trick or not. If the leader wins the trick, his adversary reckons nothing that trick; but if the second player wins the trick he also counts one; and so on. The winner of the last trick counts two instead of one.

The tricks are left face upwards on the table, in front of the player who wins them. They may be examined by either player at any time.

If each player wins six tricks the cards are *divided*, and there is no further score. If one player wins more than six tricks he wins *the cards*, and adds ten to his score. If one player wins every trick, he wins a *capot*, and scores forty for the cards, instead of ten.

During the play of the hand, a player is entitled to be informed as to any cards his adversary holds which he has reckoned as good, or has declared to be equal. A player may require his adversary to exhibit any such cards; but the usual practice is to reply to all necessary questions with regard to them, such as "how many of your point?" meaning how many in hand, "how many of your tierce?" and so on.

During the progress of the hand each player repeats aloud the amount of his score for the time being (see example). At the end of the hand the number scored is recorded on a ruled card. Each player has a card and writes down the scores of both himself and his opponent. At the end of the sixth hand, the totals are recorded, and the necessary subtraction or addition made. The scores are then compared. If there is any difference in the written scores, a player's score of his own hand is deemed to be the correct one.

Example.—A (elder hand) has dealt him ace, king, knave of spades; ace, queen, knave, eight of hearts; knave, eight, seven of clubs; and nine, eight of diamonds. He discards king of spades; eight, seven of clubs; and nine, eight of diamonds. He takes in nine, eight of spades; king of hearts; nine of clubs; and king of diamonds.

B (younger hand) has ten, seven of spades; ten, nine, seven of hearts; king, queen, ten of clubs; and ace, queen, knave, ten of diamonds. He discards seven of spades; and nine, seven of hearts. He takes in queen of spades; ace of clubs; and seven of diamonds.

The hand then proceeds thus. A (calls his point) "five cards." B (says) "equal," or "what do they make?"

A "forty-nine," or "making nine." B "good."

A (counting his point) "five" and (counting his sequence, which is good) "a quart major, nine. Three knaves?" B "not good."

A (leads ace of hearts and says) "ten." B "four tens, fourteen, and three queens, seventeen" (plays the ten of hearts).

A (leads the remaining hearts and says) "eleven, twelve, thirteen, fourteen." B (plays seven, ten, knave, queen of diamonds, and repeating his score, says) "seventeen."

A has now five tricks, and in order to win the cards should lead any card but a high spade. He leads king of diamonds, and says "fifteen." B (wins with ace and says) "eighteen," (and then leads the winning clubs, saying) "nineteen, twenty, twenty-one, twenty-two."

A (keeps ace, knave of clubs, and repeating his score says) "fifteen." B (leads queen of spades and says) "twenty-three."

A (wins with ace and says) "sixteen" (and leads knave, saying) "eighteen" (and adding ten for the cards) "twenty-eight."

A then writes on his scoring card 28; 23. B writes on his 23; 28. The pack is collected, and the next hand commences.

Three scores (omitted in order to simplify the description of the game) have yet to be mentioned.

Carte Blanche.—If either player has neither king, queen, nor knave in the hand dealt him, he holds *carte blanche*, for which he scores ten. As soon as a player discovers he has a *carte blanche*, he must tell his adversary; this he usually does by saying "discard for *carte blanche*." The adverse discard is then made (as explained under discarding), after which the *carte blanche* is shown by dealing the cards quickly one on top of the other, face upwards on the table.

Pique.—If the elder hand scores, *in hand and play*, thirty or more, before the younger counts anything, he gains a *pique*, for which he adds thirty to his score. For example, A has a quint major, good for point and sequence, and three aces, also good. For these he counts twenty-three in hand. He next leads the quint major (twenty-eight), one of the aces and another card, making him thirty. He then adds thirty for the pique and calls his score "sixty."

Repique.—If a player scores, *in hand alone*, thirty or more, before his adversary reckons anything, he gains a *repique*, for which he adds sixty to his score. Thus, point, quint, and quatorze, all good, make thirty-four. A player holding these adds sixty for the repique, and calls his score "ninety-four."

The order in which the scores accrue is of importance. For the sake of convenience, the elder hand finishes his reckoning before the younger begins. The scores, however, whether made by the elder or younger hand are *recordable* in the following order:—(1) *carte blanche*; (2) point; (3) sequences; (4) quatorzes and trios; (5) points made in play; (6) the cards. This will often affect a pique or repique. Thus, a pique can only be made by the elder hand, as the one he reckons in play when he leads his first card counts before points subsequently made in play by the younger hand. The younger, therefore, cannot make thirty *in hand and play* before the elder scores one. But the one reckoned by the elder hand when he leads his first card does not prevent his being repiqued, because scores made *in hand* have precedence of points made *in play*. The elder leads his first card and counts for it before the younger reckons, simply as a convenient way of stating that he has nothing *in hand* which is good. Again, say A has a quint (good), a tierce, and a quatorze (good). He scores thirty-two in hand alone; but, if his point is not good, he does not gain a repique, because the younger hand's point is recordable in order before the sequences and quatorze. And again, say A has a *huitieme* (good for twenty-six), and a tierce, and leads a card thus reaching thirty in hand and play. B has three tens. The trio reckoning in order before the point made in play by A saves a pique.

Carte blanche, taking precedence of all other scores, saves piques and repiques. It also counts towards piques and repiques. Thus, a player showing *carte blanche*, and having point and quint, both good, would repique his adversary.

A *capot* does not count towards a pique, as the *capot* is not made *in play*. It is added after the play of the hand is over.

A player who reckons nothing that hand as a penalty (see "Laws") is not piqued or repiqued if he holds any cards which, but for the penalty, would have reckoned before his adversary reached thirty.

Equalities do not prevent piques or repiques. A player who has an equal point or sequence scores nothing for it. Therefore if, notwithstanding the equality, a player makes thirty, in hand and play, or in hand, by scores which reckon in order before anything his adversary can count, he gains a pique or a repique.

Hints to Players.—On taking up your hand look for *carte blanche*. Before discarding, ascertain what there is against you. Thus: if you have knave or ten of a suit, there is no quint against you in that suit.

When discarding, elder hand, your main object is to plan an attack. Younger hand, on the contrary, should guard his weak places and then see if he has a chance of attacking anywhere. Thus, the elder hand may freely unguard kings and queens, or discard whole suits of which he has indifferent cards only. The younger should do just the reverse, keeping guards to kings and queens, and should not leave himself blank of a weak suit, as his small cards may guard high ones taken in.

In most hands, and especially younger hand, it is essential to keep the whole of your best suit for point. Gaining the point makes an average difference of at least ten to the score; and, what is of more consequence, it saves piques and repiques.

The cards are next in importance to the point. In discarding you should, when in doubt, take the best chance of dividing or winning the cards. Winning the cards instead of losing them makes a difference of about twenty-three points. Hence, especially elder hand, you should not necessarily keep the longest suit for point, if that suit is composed of low cards, and keeping it involves the discard of high cards from other suits.

As a rule, it is not advisable to leave any cards. The younger hand is at less disadvantage in leaving a card than the elder; for a card left by the elder can be taken by the younger; but a card left by the younger is only excluded from his hand. A card may generally be left when there is a chance of a great score if the cards in hand are not parted with, there being at the same time no pique or repique against you.

It is generally right to keep unbroken suits. Having made up your mind to discard from a given suit, you should throw the whole of it, except (a) winning cards; (b) guards to kings or queens, especially younger hand; or (c) cards which make up a quatorze or trio. It is better to keep cards in sequence than cards not in sequence. Trios should be kept if they can be retained without injury to the hand in other respects; but it is seldom advisable to put out a high card for the sake of keeping a trio of knaves or tens, especially if there is a quatorze against you.

The discard is further affected in the last hand of a *partie* by the state of the score. Thus, if you are a long way behind, and your only chance is a desperate discard, in order to keep cards which may possibly give you a pique or a repique, you may run considerable risk with that object. On the other hand, if you are well ahead, make a safe discard, *i.e.*, one which is likely to win the cards or to keep your adversary back.

When taking in after discarding, count that you leave the full number of cards for the younger hand, the penalty for taking in one of your adversary's cards being that you can reckon nothing

that deal. The younger hand should also count that the proper number of cards are in the stock, before he takes in, as, if he mixes one of the elder's cards with his hand, he can reckon nothing that deal.

After taking in and before calling your hand, look through it and your discard to ascertain what remains against you. If there is anything against you which is not called, you will probably be able to judge from this some portion of the discard, and will so be assisted in playing the cards. But implicit reliance must not be placed on this. For experienced players not unfrequently omit to call some small score, such as a tierce, in order intentionally to mislead you. This manœuvre (called *sinking* a score) is especially resorted to when a player has a high card unguarded. In order to induce you to believe that it is guarded, he will put up with the loss of several points in calling, on the chance of recouping himself by afterwards saving or winning the cards in consequence of your misconceiving his discard.

If your adversary calls a point which is not good, you should at once note in which suit it is (or may be), in order to count the hand. If the younger hand admits a point to be good (as regards the number of cards that compose it), the elder should observe whether the younger could possibly have had equal or better in any suit. If so he has probably put out that suit. But it may be that the younger hand, if a good judge of the game, will admit the number of cards of a point to be good when he has an equal number. Thus:—A calls five cards, and B knows, from examining his hand and discard, that there is only one suit in which A can have five cards, and that they make fifty. B has five cards making forty-nine. B should promptly reply "good," although he has five cards himself; because he ought to know that A's five cards are better than his. By saying "equal," he unnecessarily exposes his hand.

In playing the cards, you must be guided a good deal by what your adversary has called, and, to some extent, by what he has not called. You will generally know several cards in the adverse hand, or will be able to mark some that have been put out. Sometimes you will know all the cards. Thus, if the younger hand fails to follow suit to your first lead in which you could only have five cards, it is evident he has put out three cards of that suit, and you know every card in his hand.

Falling direct indications, lead the point, unless you have a small point and there is a tenace in that suit against you.

When playing to the opponent's lead, keep guards to kings and queens. Having the choice between throwing a card you have declared and one you have not, prefer the former.

If you can make a pique, lead your winning cards one after the other, without considering how many of the remaining tricks you will lose. There is one exception to this:—in the sixth hand, if your losing the cards will enable the younger hand to save his rubicon, and your score is such that you can win the *partie* without the pique, you should forego the pique, when by not leading out your winning cards immediately you can divide or win the cards.

When you have five or six tricks and a winning card, lead the winning card, unless certain that your opponent has cards of that suit. By playing otherwise, you risk eleven points for the chance of gaining one for the last trick. This, of course, is liable to a similar exception as the previous case, viz., in the sixth hand with five tricks up, if you must win the cards or the last trick to win the *partie* or to save the rubicon.

In the sixth hand, if a player has scored less than a hundred, he should consider, before calling or playing, whether he can make his aggregate score up to a hundred or more. If he cannot, his object should be to reckon as little as he can, and to prevent his adversary from scoring, by making his point or sequence equal (if possible), and by endeavouring to divide the cards. If he is satisfied he cannot divide the cards, and there is no capot against him, he is at liberty to score two (one for a trick he wins, and one for a card he plays), and to throw his cards down, allowing the adversary to reckon thirteen in play.

On the other hand, a player who is ahead, and who sees his adversary cannot reach a hundred, should endeavour to prevent the declaration of equalities, and, if he cannot win the cards himself, should play to lose them.

During the calling and play of the hand, always keep in mind your adversary's score and satisfy yourself that he does not reckon too many. Mistakes occur, even among the most honourable players. If your adversary reckons too few, you are not bound to correct him.

Laws of Piquet.—1. A player may shuffle either pack, above the table. The dealer has the right to shuffle last. 2. A cut must consist of at least two cards. 3. Highest has choice of deal and cards. (Ace highest, seven lowest.) 4. If a card is exposed in cutting or before dealing, there must be a fresh cut. 5. The mode of distributing the cards (by twos or by threes) must not be altered during the *partie*. 6. The stock must be placed, in one packet, face downwards, between the players. 7. If the cards are dealt wrongly, the error may be rectified before either player has taken up his hand, or the adversary may demand a fresh deal. 8. If a card belonging to the elder hand or the stock is exposed when dealing, the adversary has the option of a fresh deal. If there is a faced card in the pack, there must be a fresh deal.

9. If, after the deal is completed, more than one card is found to have been dealt wrongly, or nine cards are found in the stock, there must be a fresh deal. The same if the wrong pack is dealt with, and the error is discovered before either player has taken up his cards; otherwise the packs remain changed. 10. If only one card has been dealt wrongly, the elder hand, after looking at his cards and before taking in a card, has the option of a fresh deal, and if there are only seven cards in the stock, he may alter his discard (see Laws 12 &c.). 11. The players deal alternately. If a player deals out of turn, and the error is discovered by either player before he takes up his cards, the deal is void, and the right dealer deals. If the error is discovered later, the elder hand must deal twice running with his own pack, unless that or the next deal is the last of the *partie*. 12. Each player is bound to discard at least one card (but see Laws 21, 22, and 23). 13. When taking in, the cards must be taken in order from the top of the stock. 14. After taking a card, a player cannot alter his discard; and if he then takes back any of his discard, he must play with more than twelve cards (see Law 80); if after taking a card he mixes any of his hand with his discard, he must play with less than twelve cards (see Law 29). 15. If either player, when taking in, exposes a card of the stock belonging to his adversary, he can reckon nothing that deal. 16. If either player mixes with his hand a card of the stock which belongs to his adversary, he can reckon nothing that deal; or the adversary may have a fresh deal. If he stands the deal he can only take in such of his cards as have not been mixed. 17. If a player discards more cards than he takes in, he must play with less than twelve cards (see Law 29). 18. If a player discards fewer cards than he takes in, he can reckon nothing that deal. 19. The adversary has the option of not enforcing the penalty of reckoning nothing that deal. 20. If the younger hand leaves any cards and mixes them with his discard, without showing them to the elder hand, the elder, after leading a card, is entitled to see the younger's discard. 21. If the elder hand elects to stand the deal when one card has been dealt wrongly, and he has thirteen cards, he must discard one card more than he takes in, and must discard at least two cards. If there are eight cards in the stock, the younger hand discards one less than he takes in, and if he only takes one card he need not discard any; if there are seven cards in the stock, and the elder hand discards six cards and takes five, the younger hand can only take two cards. 22. If the elder hand elects to stand the deal when he has eleven cards, and there are eight in the stock, he must discard one less than he takes in; if he only takes one card he need not discard any. The younger hand must discard one more than he takes in, and must discard at least two cards. 23. If the elder hand elects to stand the deal when he has twelve cards, and there are seven in the stock, he discards the same number as he takes in; the younger discards one more than he takes in, and must discard at least two cards. 24. When the elder hand's call is good against the cards, it is sufficient if he states the number of cards that compose it; if not he must say what it makes or to what card it is, or the value of the cards of which it consists. 25. The elder hand calling too little may correct his miscall before it has been replied to by the younger hand; and the younger hand, allowing a correct call to be good or equal, when he holds better, may correct his reply before the elder hand has made another call, or, if there is no further call, before the elder hand has led a card. 26. If a player calls what he does not hold, he may correct his call before the younger hand has played to the first trick; and, if the younger hand has miscalled, the elder hand may take up his card and play differently. In the absence of correction, the offender can reckon nothing that deal, and the adversary, on discovery of the error, can reckon anything he has good, which is not barred by a correct call made in addition to the miscall. But there is no penalty for calling anything which a player could not possibly hold in his hand and discard taken together, nor for misnaming a suit, nor for misnaming the rank of a sequence, when one of the counting value named is held, provided the claim could not have been held in the hand and discard taken together; and, if a player voluntarily shows what he claims for, he is liable to no penalty for miscalling it. 27. A player who calls anything which is allowed to be good or equal must show the cards called at any time they are asked for during the play of the hand. 28. When the younger hand has played to the first trick, neither player can reckon anything omitted (but see Law 26). 29. A player is liable to no penalty for playing with less than twelve cards. His adversary counts as tricks all cards that cannot be played to. 30. If a player plays with more than twelve cards, he can reckon nothing that deal; but his cards, though not good to score, are good to bar his adversary. 31. A card led or played cannot be taken up (but see Law 26), but cards accidentally dropped may be retaken. Also, if the leader leads several cards consecutively without waiting for them to be played to, and the adversary plays too many cards, he may retake the extra ones; and cards subsequently played in error must be taken up and played over again. Or, if a player leads out of turn, he may take up his card unless it has been played to. Or, if a player does not follow suit when able, the card played in error and all cards subsequently played must be taken up and played over again. Or, if a player misinforms his adversary when asked what cards he holds that have been allowed to be good or equal, the adversary may retake all the cards he has subsequently played, and may play differently. 32. Errors in counting the hand, if proved, may be rectified before the player in error has seen his next hand. 33. If both players score the same number in six deals, each deals once more, when the *partie* is concluded, even if there should be a second tie. 34. If the loser fails to score a hundred, he is rubiconed, whether the winner's score reaches a hundred or not. 35. The deal in which the discovery of an incorrect pack is made is void. All preceding deals stand good. 36. A bystander calling attention to any error or oversight, and thereby affecting the score, may be called upon to pay all stakes and bets of the player whose interest he has prejudicially affected.

See Edmond Hoyle, *A Short Treatise on the Game of Piquet* (1744); "Cavendish," *The Laws of Piquet and of Rubicon Piquet*, adopted by the Portland Club, with a Treatise on the Game (1832). (H. J.)

PIRACY. Sir Edward Coke (*Instit.* iii. 113) describes a pirate (Latin *pirata*, from Greek *πειρατής*) as *hostis humani generis*, and as a rover and robber upon the sea. Piracy may be defined in law as an offence which consists in the commission of those acts of pillage and violence upon the high seas which on land would amount to felony. By the ancient common law of England piracy, if committed by a subject, was deemed to be a species of treason, being contrary to his natural allegiance, and by an alien to be felony; but since the Statute of Treasons, 25 Edw. III. c. 2 (1351–52), piracy has been held to be felony only. Formerly this offence was only cognizable by the Admiralty courts, whose proceedings were based upon the

civil law, but by the statute 28 Hen. VIII. c. 15 (1536) a new jurisdiction proceeding according to the common law was set up which, modified and regulated by subsequent enactments, such as 39 Geo. III. c. 37 (1798-99), 4 & 5 Will. IV. c. 36 (1834), and 7 & 8 Vict. c. 2 (1844), continues to be the tribunal by which offenders of this description are tried.

Piracy, being a crime not against any particular state but against all mankind, may be punished in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the law of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), it is not allowed to kill them without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

The earliest of all sea-rovers were perhaps the Phœnicians. During the heroic age of Greece piracy was universally practised. In the Homeric poems frequent mention is made of piracy, which indeed was held in honourable estimation,—the vocation of a pirate being recognized, so that a host, when he asked his guest what was the purpose of his voyage, would enumerate enrichment by indiscriminate maritime plunder as among those projects which might naturally enter into his contemplation. So late as the time of Solon the Phœceans, on account of the sterility of their soil, were forced to roam the seas as pirates. That legislator tolerated whilst he regulated the association of sea-rovers which he found established by inveterate usage. The prevalence of the piratical spirit in Greece in the early ages may perhaps be explained by the number of small independent states into which the country was divided, and the violent animosity subsisting among them. In this way predatory habits were diffused and kept alive. As a more regular system of government grew up, and a few states such as Athens and Corinth had become naval powers, piracy was made a capital offence. It was, however, never entirely put down. Cilicia was at all times the great stronghold of the pirates of antiquity, and in consequence of the decline of the maritime forces which had kept them in check they increased so much in numbers and audacity as to insult the majesty of Rome itself, so that it became necessary to send Pompey against them with a large fleet and army and more extensive powers than had ever previously been conferred on any Roman general. The Etruscans were notorious sea-rovers who infested the Mediterranean; and Polybius relates that the Romans imposed upon the Carthaginians as a condition of peace the stipulation that they should not sail beyond Cape Faro, either for the purposes of trade or piracy.

Hallam (*Middle Ages*, iii. 336) says that in the 13th and 14th centuries a rich vessel was never secure from attack, and neither restitution nor punishment of the criminals was to be obtained from Governments. Hugh Despenser seized a Genoese vessel valued at 14,300 marks, for which no restitution was ever made. The famous Hanseatic League was formed in the middle of the 13th century in northern Germany chiefly for the purpose of protecting the ships of the confederated cities from the attacks of the pirates by which the Baltic was then infested.

A graphic account of piracy as it existed at the end of the 16th century in European waters, especially on the English, French, and Dutch coasts, will be found in Motley, *Hist. United Netherlands* (vols. iii. and iv.). The nuisance was not abated in Europe until the feudal system had been subverted and the ascendancy of the law finally secured. In more modern times some of the smaller West India Islands became a great resort of pirates, from which,

however, they have for many years been driven; for continued acts of piracy the city of Algiers was successfully bombarded by the British fleet under Lord Exmouth as lately as August 1816; and pirates are still not unfrequently met with in the Indian and Chinese seas, but piracy in its original form is no longer in vogue. The BUCCANEERS (*q.v.*) were cruel piratical adventurers of a later date who commenced their depredations on the Spaniards soon after they had taken possession of the American continent and the West Indies, although there was a time when the spirit of buccaneering approached in some degree to the spirit of chivalry in point of adventure. Scaliger observes in a strain of doubtful compliment, "Nulli melius piraticam exercent quam Angli." The first levy of ship money in England in 1635 was to defray the expense of chastising these pirates. The buccaneering confederacy was broken up through the peace of Ryswick in 1697.

At a very early period of English history the law provided for the restitution of property taken by pirates, if found within the realm, whether belonging to strangers or Englishmen; but any foreigner suing for the recovery of his goods was required to prove that at the time of the capture his own sovereign and the sovereign of the captor were in mutual amity, for it was held that piracy could not be committed by the subjects of states at war with each other. In England the crown is, generally speaking, entitled to all *bona piratorum*; but if any person can establish a title to the goods the claim of the crown thereto ceases. By 13 & 14 Vict. c. 26 (1850), ships and effects captured from pirates are to be restored on the payment of one-eighth of their value (by way of salvage), which is to be distributed among the recaptors.

Cowel (*Law Dict.*, 1727) states that in former times the word pirate was used in a better sense than that of a sea-robber, being attributed to persons to whose care the mole or pier of a haven was entrusted, and, quoting the learned Spelman, he adds, sometimes to a sea soldier: "Robertus vero Comes (Normaniæ) attemptavit venire in Angliam cum magno exercitu, sed a piratis Regis qui curam maris a Rege (Willielmo) susceperant repulsus est" (*Glossarium*, 1687, p. 460).

(J. C. W.)

PIRÆUS. See ATHENS.

PIRANESI, GIOVANNI BATTISTA, an eminent Italian engraver of ancient architectural subjects, was born in the former half of the 18th century, and studied his art at Rome. The great remains of that city kindled his enthusiasm and demanded portrayal. His hand faithfully imitated the actual remains of a fabric; his invention, catching the design of the original architect, supplied the parts that were wanting; his skill introduced groups of vases, altars, tombs; and his broad and scientific distribution of light and shade completed the picture, and threw a striking effect over the whole. One engraving after another was executed with much brilliancy; and, as the work went on, the zeal of the artist only waxed stronger. In course of time it was found necessary to call in the aid of all his children and of several pupils. He did not, in fact, slacken in his exertions till his death in 1778. The plates of Piranesi, in which the severity of burin work is largely supplemented by the freer lines of the etching-needle, were collected and preserved by his son and coadjutor Francesco. They were published, to the number of about 2000, in 29 vols. fol., Paris, 1835-37.

PIRMASENS, a small manufacturing town of the Bavarian palatinate, lies in a hilly district, nearly 40 miles west by south of Spire. The staple industry is the production of boots and shoes, which are exported to Austria, Russia, and even America; but musical instruments, stoneware, and other articles are also manufactured. The only noteworthy buildings are the town-house and the principal church, the latter containing a fine monument to Louis IX., landgrave

of Hesse-Darmstadt. In 1880 the town contained 12,039 inhabitants, three-fourths of whom were Protestants.

Pirmasens owes its name to a St Pirmin, who is said to have preached Christianity here in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. In 1793 the Prussians gained a victory here over a body of French troops.

PIRNA, an ancient town of Saxony, lies on the left bank of the Elbe, on the margin of the "Saxon Switzerland," 11 miles above Dresden. It is on the whole a regularly built town, with promenades on the site of the former ramparts, but contains no notable edifices except the fine Gothic Hauptkirche (1502-46) and the town-house. The chief source of its prosperity is formed by the excellent sandstone found on both banks of the Elbe above the town; but manufactures of cigars, chemicals, enamelled tinware, pottery, and leather are also carried on. Besides the export of the sandstone, it transacts a trade in grain, fruit, and timber, mainly by river. The population in 1880 was 11,680, almost all Protestants.

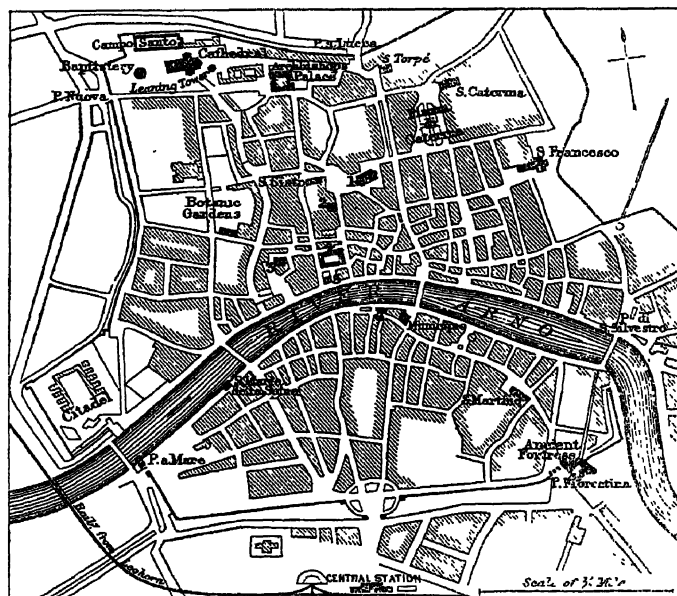

Pirna, originally a Slavonic settlement, long oscillated between Bohemia and Meissen (Saxony), but became permanently united with the latter in 1404. Having at a very early period received the privilege of holding fairs, it was at one time among the most flourishing of Saxon towns, but afterwards lost its importance through pestilence and the disasters of the Thirty Years' and Seven Years' Wars. On a rock above the town rises the fortress of Sonnenstein, now a lunatic asylum, erected in the 16th century on the site of an older castle, and once considered the most important fortress on the Elbe. It successfully withstood the Swedes in the Thirty Years' War, though the town was stormed, but was captured and dismantled by the Prussians in 1758. In 1813 it was occupied by the French, and held for several months.

PIRON, ALEXIS (1689-1773), the foremost epigrammatist of France, was born at Dijon on the 9th July 1689. His father, Aimé Piron, was an apothecary, but was also a frequent writer of verse in Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law without any success or much seriousness. As a young man he made himself notorious by the composition of a piece of licentious verse which might have brought him into serious difficulties but for the good nature of a high legal official, the president Bouhier. His sarcastic tongue made him unpopular in his neighbourhood, and at last in 1719, when nearly thirty years old, he went to seek his fortune at Paris. His first experiences were not very encouraging, and he had to put up with the unpleasant and not very honourable position of literary adviser and corrector to the Chevalier de Belle Isle. An accident, however, brought him money and notoriety. The jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage. None of the ordinary writers for this theatre, not even Lesage, would attempt a monologue-drama for the purpose, and Piron obtained a footing as a dramatic author, much applause, and three hundred crowns, with a piece called *Arlequin Deucalion*. Thenceforward he was constantly employed for this theatre, and not seldom for the more dignified Comédie Française, but with the exception of the excellent verse comedy of *La Métromanie* no one of his comedies and none of his tragedies at all deserve mention. His real vocation was that of an epigram maker, and this, though it made him not a few enemies, recommended him to not a few patrons who supplied his necessities. His most intimate associates, however, during the middle period of his life were two ladies of talent though not of position, Mademoiselle Quinault, the actress, and her friend Mademoiselle Quenaudon or De Bar, companion to a lady of rank. She was slightly older than Piron and not beautiful, but after twenty years acquaintance he married her in 1741, lived happily enough with her for four years, and nursed her tenderly during an attack of madness which

in other two years proved fatal. He long outlived her, dying on the 21st January 1773 in his eighty-fourth year. The discredit of his early literary misdeed, and perhaps his indiscriminate habits of lampooning, prevented his election to the Academy, certain persons having induced the king to interpose his veto. But Piron was pensioned, and during the last half century of his life was never in any want. He was a complete literary free-lance, and lampooned Fréron and Desfontaines as sharply as he lampooned Voltaire and the *philosophe* coterie. Socially he was a rather loose liver, though probably, except on paper, not worse than most of his contemporaries. He was a member of the somewhat famous convivial society of the *Caneau*. But his true title to remembrance lies in his epigrams, one of which, the burlesque epitaph on himself but reflecting on the Academy (see vol. viii. p. 496), is known to almost everybody, while many others equal or surpass it in brilliancy. Grimm called him a "machine à saillies," and probably no man who ever lived possessed more of the peculiarly French faculty of sharply pointed verbal wit than he. It is noteworthy too that he was as ready with conversational retort as with his pen.

Piron published his own theatrical works in 1758, and after his death his friend and literary executor Rigollet de Juvigny published his *Œuvres Complètes*. During the last thirty years a good deal of unpublished work has been added by MM. Bonhomme, Lalanne, and others. But the epigrams, which take up but little room and have been frequently reissued in various selections, are alone of great importance.

PISA, which has always been one of the most important cities of central Italy, is situated on the banks of the Arno at a short distance from the sea, in the midst of a

3. Royal Theatre.
4. University.
5. Palazzo Lanfreducci or Alla Giornata.
6. Post Office.

fertile plain backed by marble mountains wooded with pines and other forest trees. In the days of Strabo it was only two geographical miles from the sea-shore, but the continual increase of the delta at the mouth of the river has now trebled that distance. In the Middle Ages the Arno was still navigable for all ships of war then in use, and formed the safest of harbours.

The origin of Pisa is very ancient, and is involved in obscurity. The Romans believed it to date from the days of Troy, and also gave a legendary account of its foundation by colonists from Greece. Strabo mentions it as one of the bravest of the Etruscan cities. From Polybius we learn that in 225 B.C. it was already the friend of the Romans:

and later it became their ally and was defended by them from the ferocious onslaughts of the Ligurian and Apuan tribes. Thus the Romans acquired great power over the city, and finally subjected it to their rule. In Cæsar's time according to some writers, in that of Augustus according to others, they established a military colony there. Nevertheless, excepting some inscriptions, sarcophagi, statues, and columns, very few remains of Roman buildings have been discovered in Pisa. Little is known of the history of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to regain its independence. Under the Byzantine dominion Pisa, like many other of the maritime cities of Italy, profited by the weakness of the Government at Constantinople to reassert its strength. And even during the first years of the harsh Lombard rule the need recognized by these oppressors of defending the Italian coast from the attacks of the Greeks was favourable to the development of the Pisan navy. Few particulars are extant concerning the real condition of the town; but we occasionally find Pisa mentioned, almost as though it were an independent city, at moments when Italy was overwhelmed by the greatest calamities. According to Amari's happy expression, "it was already independent by sea, while still enslaved on land." Its prosperity notably declined after the re-establishment of the Lombard rule and under the Franks. It again began to flourish under the marquises of Tuscany, who governed it in the name of the emperor.

In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the Middle Ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. And, although the numerous legends and fables of the old chroniclers disguise the true history of this struggle, they serve to attest the importance of Pisa in those days. In 1004 the Saracens forced the gates and sacked a quarter of the town; and in 1011 they renewed the attack. But the Pisans repulsed them and assumed the offensive in Calabria, Sicily, and even in Africa. Still more memorable was the expedition afterwards undertaken by the united forces of Pisa and Genoa against Mogâhid, better known in the Italian chronicles as Mugeto. This Moslem chief had made himself master of Sardinia, and was driven thence by the allied fleets in 1015. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native magistrates, who were like petty sovereigns, but were now subject to the sway of Pisa. This was the primary cause of the jealousy of the Genoese, and of the wars afterwards made by them upon Pisa and carried on until its power was crushed. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di Mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor Henry IV., that supplies the first authentic notice of the existence of consuls in mediæval Italy.¹ The oldest of Pisan statutes still extant is the *Breve dei Consoli di Mare* of 1162.

¹ It must be remembered that the Pisans and Florentines dated the beginning of the year *ab incarnatione*, i.e., from the 25th March. But the Florentines dated it from the 25th following and the Pisans from the 25th March preceding the commencement of the common year. The new or common style was adopted throughout Tuscany in the year 1750.

In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses, and privileges of all kinds in every Eastern port. Thus, while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese, and Moslems. In 1110 Pisa made peace with Lucca after six years of continuous hostilities. And between 1114 and 1116 it achieved a still greater enterprise. The Pisan fleet of three hundred sail, commanded by the archbishop Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Moslems, and returned loaded with spoil and with a multitude of Christian and Moslem prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. The chief eunuch who had governed Majorca perished in the siege. Immediately afterwards the fourteen years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor Lothair II., the Pisans entered the Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. It has been said that the copy of the Pandects, then taken by the Pisans from Amalfi was the first known to them, but in fact they were already acquainted with those laws. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Moslems (1187) the Pisans and Genoese again met in conflict in the East, and performed many deeds of valour. They were always ready to come to blows, and gave still more signal proofs of their enmity during the Sicilian war in behalf of the emperor Henry VI. From that moment it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the erection of the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistery was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

It is asserted by some writers, especially by Tronci, that in the 12th century Pisa adopted a more democratic form of government. But in fact the chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelf and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. The independence of the former city was of much later origin,

only dating from the death of Countess Matilda (1115), but it rapidly rose to an ever-increasing power, and to inevitable rivalry with Pisa. Owing to the political and commercial interests binding Florence to the Roman court, the Guelf element naturally prevailed there, while the growth of its trade and commerce necessarily compelled that state to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a glorious resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a most ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog. This merely shows that there were already so many general and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched fifty-two galleys to assist Frederick II. in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia. The judges who governed the island were always at strife, and, as some of them applied to Pisa and some to Genoa for assistance against one another, the Italian seas were once more stained with blood, and the war burst out again and again, down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca, and all the Guelf cities of Tuscany against its Ghibelline rival. The pope had excommunicated Frederick II. and all his adherents. And, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia, and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now twelve elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of forty members. The rout of the Tuscan Guelfs on the field of Montaperto (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstauffen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelf and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. The first man to step to the front at this moment was Count Ugolino della Gherardesca of the powerful house of that name. He had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the Guelfs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman Giovanni Visconti, judge of Gallura; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor to his party, his country, and his kin. So in 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid

waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms,—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino, whose houses they had burnt, and whose lands they had confiscated. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On the 6th August 1284 the great battle of Meloria took place. Here seventy-two Pisan galleys engaged eighty-eight Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She had lost her dominion over the sea, and the Tuscan Guelfs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters, he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca, and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi, and Gualandi, and a section of the popular party. The city was plunged into civil war. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After a day's fighting (1st July 1288) the count, his two sons, and his two nephews were captured in the Palazzo del Popolo (or town hall), and cast into a tower belonging to the Gualandi and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate, opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. Their own internal dissensions of 1293 put a stop to the campaign, but not before they had concluded an advantageous peace. They and all the members of the Guelf league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba they were exempted from every tax. They likewise received a ransom of 160,000 lire for their Pisan prisoners. These were no longer numerous, many having succumbed to the hardships and sufferings of all kinds to which they had been exposed.

In 1312 the arrival of the emperor Henry VII. gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Uguccione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown, he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on the 29th August 1315. So tyrannical, however, was his rule that in 1316 he was expelled by the popular

fury. But Pisa's freedom was for ever lost. He was succeeded by other lords or tyrants, of whom the most renowned was Castruccio Castracane, a political and military adventurer of much the same stamp as Uguccione himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them for ever; but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan, and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (2nd October), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then, in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Giovan Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa, and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son Gabriele Maria Visconti, who was afterwards expelled from its gates. But even during this century of disaster the Pisans continued to cherish the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Niccola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and Orcagna painted his celebrated frescos on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on the 9th October, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine Government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner

course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not hesitate, even in his presence, to assert their own independence, and, casting the Florentine ensign, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all their crops. Soderini, who was perpetual gonfalonier of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 the latter encamped his forces on three sides of the distressed city, which at last, reduced to extremity by famine, was forced to surrender on the 8th June 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions, which were freely distributed to all; they tried to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland, and the south of France, we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well-disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand-duke Cosmo I., a genuine statesman, not only restored the university, but instituted the "Uffizio dei Fossi," or drainage office for the reclamation of marsh lands, and founded the knighthood of St Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (see MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1595. These dreary times, however, are brightened by one glorious name—that of Galileo Galilei. A native of Pisa, he taught in its university; he made his first experiments in gravity from its bell tower, discovered, by observing the swing of the cathedral lamp, the law of the oscillation of the pendulum, and began there his stupendous reform of natural philosophy. But the sufferings inflicted on him by the Inquisition prove the depth of ignorance to which Tuscany and all Italy had then sunk.

As to Pisa, it is enough to mention that its population within the walls had been reduced in 1551 to 8574 souls, and that by 1745 it had only risen to the number of 12,406. Under the house of Lorraine, or more correctly during the reign of that enlightened reformer Pietro Leopoldo (1765–1790), Pisa shared in the general prosperity of Tuscany, and its population constantly increased. By 1840 it contained 21,670 souls, exclusive of the suburbs and outlying districts. At the present day Pisa is again one of the most flourishing cities of Tuscany. It counts 37,704 inhabitants within the walls, and in-

cluding the suburbs a total of 53,957. Its university is one of the best in Italy; it is an important railway centre; its commerce and manufactures are continually on the increase; its agriculture is rich and flourishing; and it is the chief city of a province numbering 283,563 inhabitants.

See P. Tronci, *Annali Pisani*, 2 vols., Pisa, 1868–1871; Roncioni, "Istorie Pisane," in the *Archivio Storico Italiano*, vol. vi. pt. 1; "Cronache Pisane," in the same *Archivio*, vol. vi. pt. 2; Repetti, *Dizionario Geografico Storico della Toscana*, s.v. "Pisa." (P. V.)

A few details regarding the principal buildings may be given by way of supplement to the foregoing article. The architects of the cathedral were Boschetto and Rinaldo, both Italians, probably Pisans. It is in plan a Latin cross, with an internal length of 311½ feet and a breadth of 252 feet. The nave, 109 feet high, has double vaulted aisles and the transepts single aisles; and at the intersection of nave and transepts there is a cupola. The basilica is still the predominant type, but the influence of the domed churches of Constantinople and the mosques of Palermo is also apparent. The pillars which support the nave are of marble from Elba and Giglio; those of the side aisles are the spoils of ancient Greek and Roman buildings brought by the Pisan galleys. Externally the finest part of the building is the west front, in which the note struck by the range of arches running round the base is repeated by four open arcades. Of the four doors three are by John of Bologna, who was greatly helped by Francavilla, Tacca, and others; that of the south side, of much older date, is generally supposed to be the work of Bonanno. Of the interior decorations it is enough to mention the altars of the nave, said to be after designs by Michelangelo, and the mosaics in the dome and the apse, which were among the latest designs of CIMABUE (q.v.). The baptistery was completed only in 1278, and marred in the 14th century by the introduction of Gothic details. The building is a circle 100 feet in diameter, and is covered with a cone-surmounted dome 190 feet high, on which stands a statue of St Raniero. The lowest range of semicircular arches consists of twenty columns and the second of sixty; and above this is a row of eighteen windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Niccolò PISANO (q.v.). The campanile or "leaning tower of Pisa" is a round tower, the noblest, according to Freeman, of the southern Romanesque. Though the walls at the base are 13 feet thick, and at the top about half as much, they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by fifteen columns, and above this rise six arcades with thirty columns each. The eighth story, which contains the bells, is of much smaller diameter than the rest of the tower, and has only twelve columns. It is less to the beauty of its architecture, great though that is, than to the fact that, being 11 feet 2 inches (or if the cornice be included 13 feet 8 inches) out of the perpendicular, it strikes the imagination in a way peculiarly its own. The entire height is 183 feet, but the ascent is easy by a stair in the wall, and the visitor hardly perceives the inclination till he reaches the top and from the lower edge of the gallery looks "down" along the shaft receding to its base. There is no reason to suppose that the architects, Bonanno and William of Innsbruck, intended that the campanile should be built in this oblique position; it would appear to have assumed it while the work was still in progress. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1188–1200), who made the spot peculiarly sacred by bringing fifty-three shiploads of earth from Mount Calvary. The building, erected in the Italian Gothic style between 1278 and 1283, by Giovanni Pisano, is of special interest chiefly for its famous frescoes noticed above (see also ORCAGNA, vol. xvii. p. 815).

PISA, LEONARDO OF. See PISANUS.

PISANELLO. See PISANO, VITTORE.

PISANO, ANDREA. Andrea da Pontadera (c. 1270–1348), generally known as Andrea Pisano, the chief pupil of GIOVANNI PISANO (q.v.), was born about 1270, and first learned the trade of a goldsmith, as did many other afterwards celebrated artists. This early training was of the greatest value to him in his works in bronze, to which the manipulation of the precious metals gave precision of design and refinement of execution. He became a pupil of Giovanni Pisano about 1300, and worked with him on the sculpture for S. Maria della Spina at Pisa and elsewhere. But it is at Florence that his chief works were executed, and the formation of his mature style was due rather to Giotto

than to his earlier master. Of the three world-famed bronze doors of the Florentine baptistery, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336.¹ This marvellous piece of bronze work, in many respects perhaps the finest the world has ever seen, has all the breadth of a sculptor's modelling, with the finish of a piece of gold jewellery. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues (see the figure), and the rest scenes from the

Part of the first bronze door of the Baptistery at Florence, by Andrea Pisano.

life of the Baptist. In design the panels owe much to Giotto: the composition of each is simple and harmonious, kept strictly within the due limits of the plastic art, no attempt at pictorial effects and varied planes being made,—in this very unlike the perhaps more magnificent but less truly artistic reliefs on the third door, that last executed by Ghiberti. Andrea Pisano, while living in Florence, also produced many important works of marble sculpture, all of which show strongly Giotto's influence. In some cases probably they were actually designed by that artist, as, for instance, the double band of beautiful panel-reliefs which Andrea executed for the great campanile. The subjects of these are the Four Great Prophets, the Seven Virtues, the Seven Sacraments, the Seven Works of Mercy, and the Seven Planets. The duomo contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect to the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The exact date of his death is not known, but it must have been shortly before the year 1349.

Andrea Pisano had two sons, Nino and Tommaso,—both, especially the former, sculptors of considerable ability. Nino was very successful in his statues of the Madonna and Child, which are full of human feeling and soft loveliness,—a perfect embodiment of the Catholic ideal of the Divine Mother. Andrea's chief pupil was Andrea di Cione, better known as ORCAGNA (q.v.). Balduccio di Pisa, another, and in one branch (that of sculpture) equally gifted pupil, executed the wonderful shrine of S. Eustorgio at Milan—a most magnificent mass of sculptured figures and reliefs.

PISANO, GIOVANNI (c. 1250–1330), son of NICCOLÒ PISANO (see below), born about 1250, was but little inferior to his father either as an architect or a sculptor. Together

¹ The date on the door, 1330, refers to the completion of the wax model, not of the casting, which was at first unsuccessful, and had to be done over again by Andrea himself.

with Arnolfo del Cambio and other pupils, he developed and extended into other parts of Italy the renaissance of sculpture which in the main was due to the extraordinary talent of that distinguished artist. After he had spent the first part of his life at home as a pupil and fellow-worker of Niccola, the younger Pisano was summoned between 1270 and 1274 to Naples, where he worked for Charles of Anjou on the Castel Nuovo. One of his earliest independent performances was the Campo Santo at Pisa, finished about 1283; along with this he executed various pieces of sculpture over the main door and inside the cloister. The richest in design of all his works (finished about 1286) is in the cathedral of Arezzo,—a magnificent marble high altar and reredos, adorned both in front and at the back with countless figures and reliefs—mostly illustrative of the lives of St Gregory and St Donato, whose bones are enshrined there. The actual execution of this was probably wholly the work of his pupils. In 1290 Giovanni was appointed architect or “capo maestro” of the new cathedral at Siena, in which office he succeeded Lorenzo Maitani, who went to Orvieto to build the less ambitious but equally magnificent duomo which had just been founded there. The design of the gorgeous façade of that duomo has been attributed to him, but it is more probable that he only carried out Maitani's design. According to Vasari, Giovanni and other pupils of Niccola also executed the bas-reliefs on the west front of Orvieto, but this assertion is unsupported by any documentary evidence. At Perugia, Giovanni built the church of S. Domenico in 1304, but little of the original structure remains. The north transept, however, still contains his beautiful tomb of Benedict XI., with a sleeping figure of the pope, guarded by angels who draw aside the curtain (see woodcut).

Part of the tomb of Benedict XI., by Giovanni Pisano.

Above is a sculptured plinth supporting canopied figures of the Madonna and other saints. The whole composition is framed by a high cusped and gabled arch, on twisted columns, enriched with glass mosaic in the style of the Cosmati. The general design is like the earlier tomb of Cardinal de Braye at Orvieto, the work of Giovanni's fellow-pupil, Arnolfo del Cambio.

One of Giovanni's most beautiful architectural works is the little chapel of S. Maria della Spina, on the banks of the Arno in Pisa; the actual execution of this gem-like chapel, and the sculpture with which it is adorned, was mostly the work of his pupils.¹ This exquisite little building has recently been pulled down and rebuilt, under the pretext of “restoration.”

The influence of his father Niccola is seen strongly in all

Giovanni's works, but especially in the pulpit of S. Andrea at Pistoia, executed about 1300. In design it resembles that in the Pisan baptistery; but the reliefs are less severely classical, and more full of vivid dramatic power and complicated motives. Another pulpit, designed on the same lines, was made by him for the nave of Pisa cathedral between 1310 and 1311. Only fragments of this now exist, but it is in course of restoration. The last part of Giovanni's life was spent at Prato, near Florence, where with many pupils he worked at the cathedral till his death about 1330.

PISANO, NICCOLA (c. 1206–1278), one of the chief sculptors and architects of mediæval Italy, was born about 1206. Though he called himself *Pisanus*, from Pisa, where most of his life was spent, he was not a Pisan by birth. There are two distinct accounts of his parentage, both derived mainly from existing documents. According to one of these he is said to have been the son of “Petrus, a notary of Siena;” but this statement is very doubtful, especially as the word “Siena” or “de Senis” appears to be a conjectural addition. Another document among the archives of the Sienese cathedral calls him son of “Petrus de Apulia.” Crowe and Cavalcaselle, as well as the majority of modern writers, accept the latter statement, and believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Those on the other hand who, with most of the older writers, prefer to accept the theory of Niccola's origin being Tuscan suppose that he was a native of a small town called Apulia near Lucca. As is the case with the biographies of so many of those artists who lived long before Vasari's own time, that author's account of Niccola is quite untrustworthy. There is no doubt that in the century preceding Niccola Pisano's birth Apulia, and the southern provinces generally, were more advanced in the plastic art than any part of northern Italy—witness especially the magnificent architecture and sculpture in the cathedrals of Salerno, Bari, Amalfi, Ravello, and many others, in which still exist bronze doors, marble pulpits, and other works of art of great merit, dating from the 11th and 12th centuries,—a period when northern Italy produced very little art-work of any real beauty. That the young Niccola Pisano saw and was influenced by these things cannot be denied, but Crowe and Cavalcaselle, in their eagerness to contradict the old traditions, go very much too far when they deny the story, told by Vasari, of Niccola's admiration for and keen study of the remains of ancient Roman sculpture which were then beginning to be sought for and appreciated. In Niccola Pisano's works it is somewhat difficult to trace the direct influence of Apulian art, while in many of them, especially the panel-reliefs of his Pisan pulpit (see figure), classical feeling is apparent in every fold of the drapery, in the modelling of the nude, and in the dignified reserve of the main lines of the composition.

For all that, Niccola was no dull copyist; though he emancipated himself from the stiffness and unreality of earlier sculpture, yet his admiration and knowledge of the physical beauty of the human form in no way detracted from the purity and religious spirit of his subjects. Though pagan in their beauty of modelling and grace of attitude, his Madonnas are as worshipful, and his saints as saintly, as those of any sculptor the world has ever seen. With true genius he opened out to the church a new field in which all the gifts of God, even purely physical ones, were made use of and adopted as types and symbols of inward purity and love—not repudiated and suppressed as snares of the evil one. Except through his works, but little is known of the history of Niccola's life. As early

¹ See Schultz, *Denkmäler der Kunst in Unter-Italien*, vol. vii. p. 5.

as 1221 he is said to have been summoned to Naples by Frederick II., to do work in the new Castel dell' Uovo. This fact supports the theory of his southern origin, though not perhaps very strongly, as, some years before, the Pisan Bonannus had been chosen by the Norman king as the sculptor to cast one of the bronze doors for Monreale cathedral, where it still exists. The earliest existing piece of sculpture which can be attributed to Niccola is a beautiful relief of the Deposition from the Cross in the tympanum of the arch of a side door at San Martino at Lucca; it is remarkable for its graceful composition and delicate finish of execution. The date is about 1237. In 1260, as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is on the whole the finest of his works.

It is a high octagon, on semicircular arches, with trefoil cusps, supported by nine marble columns, three of which rest on white marble lions. In design it presents that curious combination of Gothic forms with classical details which is one of the characteristics of the mediæval architecture of northern Italy; though much enriched with sculpture both in relief and in the round, the general lines of the design are not sacrificed to this, but the sculpture is kept subordinate to the whole. In this respect it is superior to the more magnificent pulpit at Siena, one of Niccola's later works, which suffers greatly from want of repose and purity of outline, owing to its being overloaded with reliefs and statuettes. Five of the sides of the main octagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion, and the Doom. These are all, especially the first three, works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccola's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the sweet yet stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccola's study of the antique is most apparent (see figure). The veiled and diademed figure of the Virgin Mother,

The Adoration of the Magi, one of the panels in the pulpit of the Pisan Baptistery, by Niccolò Pisano.

seated on a throne, recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi. Certain figures in others of the panels are no less deeply imbued with classical feeling.

The next important work of Niccola in date is the Arca di San Domenico, in the church at Bologna consecrated to that saint, who died in 1221. Only the main part, the actual sarcophagus covered with sculptured reliefs of St Dominic's life, is the work of Niccola and his pupils. The sculptured base and curved roof with its fanciful ornaments are later additions. This "Arca" was made when St Dominic was canonized, and his bones translated; it was finished in 1267, not by Niccola himself, but by his pupils. The most magnificent, though not the most beautiful, of Niccola's works is the great pulpit in Siena cathedral (1268). It is much larger than that at Pisa, though somewhat similar in general design, being an octa-

gon on cusped arches and columns. Its stairs, and a large landing at the top, with carved balusters and panels, rich with semi-classical foliage, are an addition of about 1500. The pulpit itself is much overloaded with sculpture, and each relief is far too crowded with figures. An attempt to gain magnificence of effect has destroyed the dignified simplicity for which the earlier pulpit is so remarkable.

Niccola's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of basins rising one above another, each with sculptured bas-reliefs; it was begun in 1274, and completed, except the topmost basin, which is of bronze, by Niccola's son and pupil Giovanni.

Niccola Pisano was not only pre-eminent as a sculptor, but was also the greatest Italian architect of his century; he designed a number of very important buildings, though not all which are attributed to him by Vasari. Among those now existing, the chief are the main part of the cathedral at Pistoia, the church and convent of Sta Margherita at Cortona, and Sta Trinita at Florence. The church of Sant' Antonio at Padua has also been attributed to him, but without reason. Unfortunately his architectural works have in most cases been much altered and modernized. Niccola was also a skilled engineer, and was compelled by the Florentines to destroy the great tower, called the *Guarda-morto*, which overshadowed the baptistery at Florence, and had for long been the scene of violent conflicts between the Guelphs and Ghibellines. He managed skilfully so that it should fall without injuring the baptistery. Niccola Pisano died at Pisa in the year 1278, leaving his son Giovanni a worthy successor to his great talents both as an architect and sculptor.

Though his importance as a reviver of the old traditions of beauty in art has been to some extent exaggerated by Vasari, yet it is probable that he, more than any other one man, was the means of starting that "new birth" of the plastic arts which, in the years following his death, was so fertile in countless works of the most unrivalled beauty. Both Niccola and his son had many pupils of great artistic power, and these carried the influence of the Pisani throughout Tuscany and northern Italy, so that the whole art of the succeeding generations may be said to have owed the greater part of its rapid development to this one family.

On the three preceding Pisani see Perkins, *Tuscan Sculptors*, vol. i., 1864; Cicognara, *Storia della Scultura*, 1823-24; Gaye, *Kunstblatt*, 1839; Rümohr, *Italienische Forschungen*, 1837-31; Milanesi, *Documenti dell' Arte and Vita di Niccolò Pisano*, Vasari, Milanesi's ed., i. p. 293 and 481, 1882; Crowe and Cavalcaselle, *Painting in Italy*, 1864-66; Gruner, *Marmor-Bildwerke der Schule der Pisaner*, 1858; Leader Scott, *Early Italian Sculptors*, 1882; Symonds, *Renaissance in Italy: Fine Arts*, p. 100 sq., 1877; Dohme, *Kunst und Künstler Italiens*, Leipzig, 1878; *Le tre porte del Battistero di Firenze*, 1821. PISANO, VITTORE (c. 1380-1456), commonly called PISANELLO, the greatest of Italian medallists, was a native of San Vigilio sul Lago in the territory of Verona. Specimens of his work as a painter are still extant in Rome, Venice, Verona, and Pistoia, and entitle him to a place of some distinction in the history of that art. The National Gallery in London possesses a very fine specimen of Pisanello's work—a panel painted with miniature-like delicacy. For his pre-eminent position as a medallist, see NUMISMATICS, vol. xvii. p. 657. During the latter portion of his life he lived in Rome, where he enjoyed great repute.

PISANUS, LEONARDUS (Leonardo of Pisa), an Italian mathematician of the 13th century who has left the stamp of his name on a whole period in the history of the science. Of Leonardo's personal history few particulars are known. His father was called *Bonaccio*, most probably a nickname with the ironical meaning of "a good stupid fellow," while to Leonardo himself another nickname *Bigollone* (dunce, blockhead) seems to have been given. The father was secretary in one of the numerous factories erected on the southern and eastern coasts of the Mediterranean by the warlike and enterprising merchants of Pisa. Where European and Arab merchants met was at that time the right

place for learning arithmetic, and it was certainly with a view to this that the father had Leonardo sent to Bugia to continue his education. But Leonardo aimed at something higher than to make himself an accomplished clerk, and during his travels round the Mediterranean he obtained such erudition as would have gained him the name of a great scholar in much later times. In 1202 Leonardo Fibonacci (*i.e.*, son of Bonaccio) was again in Italy and published his great work *Liber Abaci*, which probably procured him access to the learned and refined court of the emperor Frederick II. Leonardo certainly was in relation with some persons belonging to that circle, when he published in 1220 another more extensive work *De Practica Geometriae*, which he dedicated to the imperial astronomer Dominicus Hispanus. Some years afterwards (perhaps in 1228, as is related by an author on the authority of a manuscript only once seen by him) Leonardo dedicated to another courtier, the well known astrologer Michael Scott, the second edition of his *Liber Abaci*, which has come down to our times, and has been printed as well as Leonardo's other works by Prince Bald. Boncompagni (Rome, 1857-62, 2 vols.). The other works consist of the *Practica Geometriae* and some most striking papers of the greatest scientific importance, amongst which the *Liber Quadratorum* may be specially signalized. It bears the notice that the author wrote it in 1225, and in the introduction Leonardo himself tells us the occasion of its being written. Dominicus had presented Leonardo to Frederick II.¹ The presentation was accompanied by a kind of mathematical performance, in which Leonardo solved several hard problems proposed to him by John of Palermo, an imperial notary, whose name is met with in several documents dated between 1221 and 1240. The methods which Leonardo made use of in solving those problems fill the *Liber Quadratorum*, the *Flos*, and a *Letter to Magister Theodore*. All these treatises seem to have been written nearly at the same period, and certainly before the publication of the second edition of the *Liber Abaci*, in which the *Liber Quadratorum* is expressly mentioned. We know nothing of Leonardo's fate after he issued that second edition, and we might compare him to a meteor flashing up suddenly on the black background of the midnight sky, and vanishing as suddenly, were it not that his influence was too deep and lasting to allow of his being likened to a phenomenon passing quickly by.

To explain this influence and the whole importance of Leonardo's scientific work, we must rapidly sketch the state of mathematics about the year 1200. The Greeks, the most geometrical nation on the earth, had attained a high degree of scientific perfection, when they were obliged to yield to the political supremacy of Rome. From this time mathematics in Europe sunk lower and lower, till only some sorry fragments of the science were still preserved in the cell of the studious monk and behind the counting-board of the eager merchant. Geometry was nearly forgotten; arithmetic made use of the abacus with counters, or with the nine characters the origin of which is still a matter of controversy (see NUMERALS); the zero was still unknown. Amongst the Arabs it was quite otherwise. Greek mathematics found amongst them a second home, where the science was not only preserved but came to new strength, and was recruited from India, whence in particular came the symbol "zero" and its use, which alone renders possible numerical calculation in the modern sense of the word. Ancient astronomy as well as ancient mathematics reappeared in Europe, from the beginning of the 12th century onwards, in an Arabian dress. Two men especially recognized the worth of these sciences and made it the task of their life to propagate them amongst their

contemporaries,—the German monk Jordanus Nemorarius and the Italian merchant Leonardus Pisanus. Leonardo, as we have said, travelled all round the Mediterranean gathering knowledge of every kind. He studied the geometry of Euclid, the algebra of Mohammed ibn Musa Alchârizmi; he made himself acquainted with Indian methods; he found out by himself new theories. So runs his own account; and an exact comparison of Leonardo's works with older sources not only confirms the truth of his narrative, but shows also that he must have studied some other authors,—for instance, Alkarchi. In his *Practica Geometriae* plain traces of the use of the Roman "agrimensores" are met with; in his *Liber Abaci* old Egyptian problems occur revealing their origin by the reappearance of the very numbers in which the problem is given, though one cannot guess through what channel they came to Leonardo's knowledge. Leonardo cannot now be regarded (as Cossali regarded him about 1800) as the inventor of that very great variety of truths for which he mentions no earlier source. But even were the predecessors to whom he is indebted more numerous than we are inclined to believe, were he the Columbus only of a territory the existence of which was unknown to his century, the historical importance of the man would be nearly the same. We must remember the general ignorance of his age, and then fancy the sudden appearance of a work like the *Liber Abaci*, which fills 459 printed pages. These pages set forth the most perfect methods of calculating with whole numbers and with fractions, practice, extraction of the square and cube roots, proportion, chain rule, finding of proportional parts, averages, progressions, even compound interest, just as in the completest mercantile arithmetics of our days. They teach further the solution of problems leading to equations of the first and second degree, to determinate and indeterminate equations, not by single and double position only, but by real algebra, proved by means of geometric constructions, and including the use of letters as symbols for known numbers, the unknown quantity being called *res* and its square *census*. We may well wonder, not that the impression caused by a work of such overwhelming character was so deep, but that it made any impression at all, and that the unprepared soil could receive the seed. The second work of Leonardo, his *Practica Geometriae* (1220), is still more remarkable, since it requires readers already acquainted with Euclid's planimetry, who are able to follow rigorous demonstrations and feel the necessity for them. Among the contents of this book we simply mention a trigonometrical chapter, in which the words *sinus versus arcus* occur, the approximate extraction of cube roots shown more at large than in the *Liber Abaci*, and a very curious problem, which nobody would search for in a geometrical work, *viz.*, to find a square number which remains a square number when 5 is added to it. This problem evidently suggested the first question put to our mathematician in presence of the emperor by John of Palermo, who, perhaps, was quite enough Leonardo's friend to set him such problems only as he had himself asked for. The problem was:—To find a square number remaining so after the addition as well as the subtraction of 5. Leonardo gave as solution the numbers $11\frac{1}{4}$, $16\frac{1}{4}$, and $6\frac{1}{4}$,—the squares of $3\frac{1}{2}$, $4\frac{1}{2}$, and $2\frac{1}{2}$; and the *Liber Quadratorum* gives the method of finding them, which we cannot discuss here. We observe, however, that the kind of problem was not new. Arabian authors already had found three square numbers of equal difference, but the difference itself had not been assigned in proposing the question. Leonardo's method, therefore, when the difference was a fixed condition of the problem, was necessarily very different from the Arabian, and, in all probability, was his own discovery. The *Flos* of Leonardo turns on the second question set by John of Palermo, which required the solution of the cubic equation $x^3 + 2x^2 + 10x = 20$. Leonardo, making use of fractions of the sexagesimal scale, gives $x = 1^0 22' 7'' 42''' 33'' 4' 40''$, after having demonstrated, by a discussion founded on the 10th book of Euclid, that a solution by square roots is impossible. It is much to be deplored that Leonardo does not give the least intimation how he found his approximative value, outrunning by this result more than three centuries. Genocchi believes Leonardo to have been in possession of a certain method called *regula aurea* by Cardan in the 16th century, but this is a mere hypothesis without solid foundation. In the *Flos* equations with negative values of the unknown quantity are also to be met with, and Leonardo perfectly understands the meaning of these negative solutions. In the *Letter to Magister Theodore* indeterminate problems are chiefly worked, and Leonardo hints at his being able to solve by a general method any problem of this kind not exceeding the first degree. We have enumerated the main substance of what appear to be Leonardo's own discoveries, and the experienced reader will not hesitate to conclude that they prove him to have been one of the greatest algebraists of any time. As for the influence he exercised on posterity, it is enough to say that Luca Pacioli, about 1500, in his celebrated *Summa*, leans so exclusively to Leonardo's works (at that time known in manuscript only) that he frankly acknowledges his dependence on them, and states that wherever no other author is quoted all belongs to Leonardus Pisanus. (M. CA.)

¹ The words "cum Magister Dominicus pedibus celsitudinis vestrae me Pisis duceret praesentandum" have always been taken to mean that Leonardo was presented to the emperor at Pisa, but the date of 1225 excludes this interpretation, as Frederick II. certainly never was in Pisa before July 1226. The translation, therefore, ought to be—"when Magister Dominicus brought me from Pisa, &c.," the place where Leonardo met the emperor remaining unknown.

PISCICULTURE. This art as at present pursued is not limited to those animals which are grouped by zoologists in the class of *Pisces*. "Fishery" is now understood to signify the exploitation of all products of the sea, lake, and river, the capture of whales, turtles, pearls, corals, and sponges, as well as of fish proper. The purpose of fish-culture (or *aquiculture*, as it is in France more appropriately named) is to counteract by reparative and also by preventive measures the destructive effects of fishery.

The possibility of exterminating aquatic animals within the restricted limits of a lake or a river cannot be doubted; authorities are decidedly at variance, however, as to the extent of the influence of man upon the abundance of life in the open seas. Distinction must be made between the extermination of a species, even in a restricted locality, and the destruction of a fishery; the former is very unusual, and is seemingly impossible in the case of oceanic species, but the latter, especially for limited regions, is of almost yearly occurrence. Aquatic mammals, such as seals, may be entirely exterminated, especially when, like the fur seal, they forsake the water for a season and resort to the land for breeding purposes. The fur seals of the Pacific and Antarctic are now nearly gone, except in two groups of islands, the Pribylows in Alaska and the Commander Islands in Siberia, where they enjoy Government protection, the islands being leased to the Alaska Commercial Company by whom only a stated number, all non-breeding males, may be killed each year, the permanence of the fishery being thus perfectly secured. Aquatic mammals also which never leave the water, like whales and sirenians, being conspicuous by reason of their size, and incapable of rapid multiplication, may, especially when they breed near the shore, suffer extermination. As examples may be cited the Arctic sea cow (*Rhytina stelleri*) and the Pacific grey whale (*Rhachianectes glaucus*), the former extinct, the latter having practically become so within the present century. The sperm whale is also rapidly disappearing. In the case of fixed animals like the oyster, the corals, and the sponges, again, the colonies or beds may be swept out of existence exactly as forests are hewn down. The native oyster beds of Europe are for the most part gone, and still more rapid has been the recent destruction of the oyster reefs in Pocomoke Sound, Maryland, a large estuary, formerly very productive—the result being due more directly to the choking up of the beds by the rubbish dragged over them by dredges, and the demolition of ledges suitable for the reception of young spat, than to the removal of all the adult oysters, which could, of course, never have been effected. The preservation of oyster-beds is a matter of vital importance to the United States, for oyster-fishing, unsupported by oyster-culture, will soon destroy the employment of tens of thousands and a cheap and favourite food of tens of millions of the people. Something may undoubtedly be effected by laws which shall allow each bed to rest for a period of years after each season of fishing upon it. It is, however, the general belief that shell-fish beds must be cultivated as carefully as are garden beds, and that this can be done only by giving to individuals rights in submerged lands, similar to those which may be acquired upon shore. It is probable that the present unregulated methods will prevail until the dredging of the natural beds shall cease to be remunerative, and that the oyster industry will then pass from the improvident fishermen to the painstaking oyster-grower, with a corresponding increase in price and decrease in consumption. Such a change has already taken place in France and Holland, and to a large extent in England, but there appear to be almost unsurmountable difficulties in the way of protecting the property of oyster-culturists from depredations—difficulties apparently as formidable in England as in America.

Fishes in ponds, lakes, or streams are quickly exterminated unless the young be protected, the spawning season undisturbed, and wholesale methods of capture prohibited. Salmon and trout streams are preserved in all countries of northern Europe; and in Canada also a large service of fishery wardens is maintained. In the United States there are in many of the older commonwealths excellent codes of laws for the preservation of fish and game, which are enforced by anglers' clubs. A river may quickly be emptied of its anadromous visitors, salmon, shad, and alewives, by over-fishing in the spawning season, as well as by dams which cut off the fish from their spawning-grounds. Numerous rivers in Europe and America might be named in which this has occurred. In the same way, sea fishes approaching the coasts to spawn in the bays or upon the shoals may be embarrassed, and the numbers of each school decimated,—particularly if, as in the case of the herring, the eggs are adhesive and become entangled in nets. Sea fishes spawning in estuaries are affected much in the same manner as the salmon in rivers, though in a less degree, by wholesale capture in stationary nets. The shad and alewife fisheries of the United States are protected by an extensive code of laws, varying in the several States and in the different rivers of each State. The most satisfactory laws appear to be those which regulate the dates when fishery must commence and end, and prescribe at least one day in each week, usually Sunday, during which the ascent of the fish may not be interrupted. Migratory, semi-migratory, or wandering fishes, ranging singly or in schools over broad stretches of ocean, the mackerels, the tunnies, the sardines or pilchards, the menhaden, the bluefish, the bonitoes, and the squeeteague, stand apparently beyond the influence of human agency, especially since, so far as is known, they spawn at a distance from the coast, or since the adults, when about to spawn, cannot be reached by any kind of fishery apparatus. Their fecundity is almost beyond comprehension, and in many instances their eggs float free near the surface, and are quickly disseminated over broad areas. The conclusions gained by Prof. Baird, U.S. commissioner of fisheries, agree exactly with those of Prof. Huxley, that the number of any given kind of oceanic fish killed by man is perfectly insignificant when compared with the destruction effected by their natural enemies. Almost any body of water, be it a bay or sound, or be it the covering of a ledge or shoal at sea, may be over-fished to such a degree that fishing becomes unprofitable, especially if fishing be carried on in the spawning season. In this manner, no doubt, have the coasts of England been robbed of the formerly abundant supplies of turbot and sole.

The character of the various destructive influences which man brings to bear upon the inhabitants of the water and their effects having thus been briefly noticed, the student of fish culture is confronted by the question, What can be done to neutralize these destructive tendencies? There are evidently three things to do:—(1) to preserve fish waters, especially those inland, as nearly as it may be possible in their normal condition; (2) to prohibit wasteful or immoderate fishing; and (3) to put into practice the art of fish breeding—(a) to aid in maintaining a natural supply, (b) to repair the effects of past improvidences, and (c) to increase the supply beyond its natural limits rapidly enough to meet the necessities of a constantly increasing population.

The preservation of normal conditions in inland waters is comparatively simple. A reasonable system of forestry and water-purification is all that is required; and this is needed not only by the fish in the streams but by the

people living on the banks. It has been shown that a river which is too foul for fish to live in is not fit to flow near the habitations of man. Obstructions, such as dams, may, in most instances, be overcome by fish ladders. The salmon has profited much by those devices in Europe, and the immense dams in American rivers will doubtless be passable even for shad and alewives if the new system of fishway construction devised by Col. McDonald, and now being applied on the Savannah, James, and Potomac, and other large rivers, fulfils its present promises of success.¹

The protection of fish by law is what legislators have been trying to effect for many centuries, and the success of their efforts must be admitted to have been very slight indeed. Great Britain has at present two schools of fishery-economists,—the one headed by Prof. Huxley, opposed to legislation, save for the preservation of fish in inland waters; the other, of which Dr Francis Day is the chief leader, advocating a strenuous legal regulation of sea fisheries also. Continental Europe is by tradition and belief committed to the last-named policy. In the United States, on the contrary, public opinion is generally antagonistic to fishery legislation; and Prof. Baird, the commissioner of fisheries, after carrying on for fourteen years, with the aid of a large staff of scientific specialists, investigations upon this very question, has not yet become satisfied that laws are necessary for the perpetuation of the sea fisheries, nor has he ever recommended to Congress the enactment of any kind of fishery laws.

Just here we meet the test problem in fish culture. Many of the most important commercial fisheries of the world, the cod fishery, the herring fishery, the sardine fishery, the shad and alewife fishery, the mullet fishery, the salmon fishery, the whitefish fishery, the smelt fishery, and many others, owe their existence to the fact that once a year these fishes gather together in closely swimming schools, to spawn in shallow water, on shoals, or in estuaries and rivers. There is a large school of *quasi* economists who clamour for the complete prohibition of fishing during spawning time. Their demand demonstrates their ignorance. Deer, game, birds, and other land animals may easily be protected in the breeding season, and so may trout and other fishes of strictly local habits. Not so the anadromous and pelagic fishes. If they are not caught in the spawning season, they cannot be caught at all.

The writer recently heard a prominent fish-culturist advocating before a committee of the United States Senate the view that shad should not be caught in the rivers because they come into the rivers to spawn. When asked what would become of the immense shad-fisheries if this were done, he ventured the remark that doubtless some ingenious person would invent a means of catching them at sea. The fallacy in the argument of these economists lies, in part, in supposing that it is more destructive to the progeny of a given fish to kill it when its eggs are nearly ripe than to kill the same fish eight or ten months earlier. We must not, however, ignore the counter-argument. Such is the mortality among fish that only an infinitesimal percentage attains to maturity. Professor Möbius has shown that for every grown oyster upon the beds of Schleswig-Holstein 1,045,000 have died. Only a very small percentage, perhaps not greater than this, of the shad or the smelt ever comes upon the breeding grounds. Some consideration, then, ought to be shown to those individuals which have escaped from their enemies and have come up to deposit the precious burden of eggs. How much must they be protected? Here the fish-culturist comes in with the proposition that "it is cheaper to

make fish so plentiful by artificial means that every fisherman may take all he can catch than to enforce a code of protection laws."

The salmon rivers of the Pacific slope of the United States, the shad rivers of the east, and the whitefish fisheries of the lakes are now so thoroughly under control by the fish-culturist that it is doubtful if any one will venture to contradict his assertion. The question is whether he can extend his domain to other species.

Fish-culture in a restricted sense must sooner or later be resorted to in all densely populated countries, for, with the utmost protection, nature unaided can do but little to meet the natural demand for fish to eat. Pond-culture (*Teichwirtschaft*), has been practised for many centuries, and the carp and the gold-fish have become domesticated like poultry and cattle. The culture of carp is an important industry in China and in Germany, though perhaps not more so than it was in England three and four centuries ago; the remains of ancient fish-stews may be seen upon almost every large estate in England, and particularly in the vicinity of old monasteries. Strangely enough, not a single well-conducted carp-pond exists in England to-day to perpetuate the memory of the tens of thousands which were formerly sustained, and the carp, escaping from cultivation, have reverted to a feral state and are of little value. Until improved varieties of carp are introduced from Germany, carp-culture can never be made to succeed in England. Carp-culture is rapidly coming into favour in the United States; a number of young scale-carp and leather carp were imported in 1877 for breeding purposes, and the fish commission has since distributed them to at least 30,000 ponds. Two railway cars especially built for the purpose are employed during the autumn months delivering cargoes of carp, often making journeys of over three thousand miles, and special shipments have been made to Mexico and Brazil. The carp is not recommended as a substitute for the salmon, but is especially suited to regions remote from the sea where better-flavoured fish cannot be had in a fresh condition.

A kind of pond-culture appears to have been practised by the ancient Egyptians, though in that country as in ancient Greece and Rome, the practice seems to have been similar to that now employed in the lagoons of the Adriatic and of Greece, and to have consisted in driving the young fish of the sea into artificial enclosures or vivaria, where they were kept until they were large enough to be used.

The discovery of the art of artificially fecundating the ova of fish must apparently be accredited to Stephen Ludwig Jacobi of Hohenhausen in Westphalia, who, as early as 1748, carried on successful experiments in breeding salmon and trout. The importance of this discovery was thoroughly appreciated at the time, and from 1763 to 1800 was a fruitful subject of discussion in England, France, and Germany. George III. of England in 1771 granted to Jacobi a life pension. It has been claimed by many French writers that the process of artificial fecundation was discovered as early as 1420 by Dom Pinchon, a monk in the abbey of Reome, but this claim is but a feeble one, not having been advanced until 1854, and it is believed by many that the practice of the French monk was simply to collect and transplant the eggs which he had already found naturally fertilized. However interesting to the antiquarian, the proceedings of Dom Pinchon had no influence upon the progress of fish-culture. To Germany, beyond question, belongs the honour of discovering and carrying into practical usefulness the art of fish-culture. Upon the estate of Jacobi, by the discoverer and his sons, it was carried on as a branch of agriculture for fully eighty years—from 1741 to 1825—though it was nearly a hundred years before public opinion was

¹ Report of United States Fish Commission for 1883.

ripe for a general acceptance of its usefulness, a period during which its practice was never abandoned by the Germans.

Fish-culture in Britain was inaugurated in 1837 by Mr John Shaw, gamekeeper to the duke of Buccleuch at Drumlanrig, who, in the course of ichthyological investigations, had occasion to fecundate the eggs of salmon and rear the young; and, as regards France, an illiterate fisherman, Joseph Remy, living in the mountains of the Vosges, rediscovered, as it is claimed, or at any rate successfully practised, in association with Antoine Gehin, the culture of trout in 1842. The originality and practical influence of Remy and Gehin's work appear to have been exaggerated by French writers. On the other hand the establishment in 1850 at Huningue (Hünningen) in Alsace by the French Government of the first fish-breeding station, or "piscifactory," as it was named by Professor Coste, is of great significance, since it marks the beginning of public fish-culture. The art discovered in Germany was practised in Italy as early as 1791 by Baufalini, in France in 1820, in Bohemia in 1824, in Great Britain in 1837, in Switzerland in 1842, in Norway under Government patronage in 1850, in Finland in 1852, in the United States in 1853, in Belgium, Holland, and Russia in 1854, in Canada about 1863, in Austria in 1865, in Australasia, by the introduction of English salmon, in 1862, and in Japan in 1877.

Artificial Propagation.—*Sponges* have been successfully multiplied by cuttings, like plants, in Austria and in Florida. *Oysters* have long been raised in artificial enclosures from spat naturally deposited upon artificial stools. The eggs of the American and Portuguese oysters have been artificially fecundated and the young hatched, and in July 1883 Mr John A. Ryder, embryologist of the U.S. Fish Commission, solved the most difficult problem in American oyster-culture by completing a mechanical device for preventing the escape of the newly hatched oysters while swimming about prior to fixation.¹ The English oyster, being hermaphrodite, or monocious, cannot be artificially propagated from the egg like the dioecious American species.

The fertilization of the *fish egg* is the simplest of processes, consisting, as every one knows, in simply pressing the ripe ova from the female fish into a shallow receptacle and then squeezing out the milt of the male upon them. Formerly a great deal of water was placed in the pan; now the "dry method," with only a little, discovered by the Russian Vrascki in 1854, is preferred. The eggs having been fertilized, the most difficult part of the task remains, namely, the care of the eggs until they are hatched, and the care of the young until they are able to care for themselves.

The apparatus employed is various in principle, to correspond to the physical peculiarities of the eggs. Fish-culturists divide eggs into four classes, viz.:—(1) heavy eggs, non-adhesive, whose specific gravity is so great that they will not float, such as the eggs of the salmon and trout; (2) heavy adhesive eggs, such as those of the herring, smelt, and perch; (3) semi-buoyant eggs, like those of the shad and whitefish (*Coregonus*); and (4) buoyant eggs, like those of the cod and mackerel. (1) Heavy non-adhesive eggs are placed in thin layers either upon gravel, grilles of glass, or sheets of wire cloth, in receptacles through which a current of water is constantly passing. There are numerous forms of apparatus for eggs of this class, but the most effective are those in which a number of trays of wire cloth, sufficiently deep to carry single layers of eggs, are placed one upon the other in a box or jar into which the water enters from below, passing out at the top. (2) Heavy adhesive eggs are received upon bunches of twigs or frames of glass plates to which they adhere, and which are placed in receptacles through which water is passing. (3) Semi-buoyant eggs, or those whose specific gravity is but slightly greater than that of the water, require altogether different treatment. They are necessarily placed together in large numbers, and to prevent their settling upon the bottom of the receptacle it is necessary to introduce a gentle current from below. For many years these eggs could be hatched only in floating receptacles with wire-cloth bottoms, placed at an angle to the current of the stream in which they were fixed, the motion of which was utilized to keep the eggs in suspension. Later an arrangement of plunging-buckets was invented, cylindrical receptacles with tops and bottoms of wire cloth, which were suspended in rows from beams worked up and down at the surface of the water by machinery. The eggs in the cylinders were thus kept

constantly in motion. Finally the device now most in favour was perfected; this is a receptacle, conical, or at least with a constricted termination, placed with its apex downward, through which passes from below a strong current, keeping the eggs constantly suspended and in motion. This form of apparatus, of which the M'Donald and Clark hatching-jars are the most perfect development, may be worked in connexion with any common hydrant.² (4) Floating eggs have been hatched only by means of rude contrivances for sustaining a lateral circular eddy of water in the receptacle.

The use of refrigerators, to retard the development of the eggs until such time as it is most convenient to take care of the fry, has been extensively introduced in the United States, and has been experimented upon in Germany.

The distinction between private and public fish-culture must be carefully observed. The maintenance of ponds for carp, trout, and other domesticated species is an industry to be classed with poultry-raising and bee-keeping, and its interest to the political economist is but slight. The proper function of public fish-culture is the stocking of the public waters with fish in which no individual can claim the right of property. This is being done in the rivers of the United States, with salmon, shad, and alewives, and in the lakes with whitefish. The use of steamships and steam machinery, the construction of refrigerating transportation cars, two of which, with a corps of trained experts, are constantly employed by the United States Fish Commission, moving fish and eggs from Maine to Texas, and from Maryland to California, and the maintenance of permanent hatching stations, seventeen in number, in different parts of the continent, are forms of activity only attainable by Government aid. Equally unattainable by private effort would be the enormous experiments in transplanting and acclimatizing fish in new waters,—such as the planting of Californian salmon in the rivers of the east, land-locked salmon and smelt in the lakes and rivers of the interior, and shad in California and the Mississippi valley, and the extensive acclimatization of German carp; the two last-named experiments carried out within a period of three years have met with successes beyond doubt, and are of the greatest importance to the country; the others have been more or less successful, though their results are not yet fully realized. It has been demonstrated, however, that the great river fisheries of the United States, which produced in 1880 48,000,000 lb of alewives, 18,000,000 lb of shad, 52,000,000 lb of salmon, besides bass, sturgeon, and smelt, and worth "at first hand" between 4,000,000 and 6,000,000 dollars, are entirely under the control of the fish-culturist to sustain or to destroy, and are capable of immense extension.

Having now attempted to define the field of modern fish-culture, and to show what it has already accomplished, it remains to be stated what appear to be its legitimate aims and limitations.

The aims of modern fish-culture, as understood by the present writer, are—(1) to arrive at a thorough knowledge of the life history from beginning to end of every species of economic value, the histories of the animals and plants upon which they feed or upon which their food is nourished, the histories of their enemies and friends, and the friends and foes of their enemies and friends, as well as the currents, temperatures, and other physical phenomena of the waters in relation to migration, reproduction, and growth; and (2) to apply this knowledge in such a practical manner that every form of fish shall be at least as thoroughly under control as are now the salmon, the shad, the alewife, the carp, and the whitefish. Its limitations are precisely those of scientific agriculture and animal rearing, since, although certain physical conditions may constantly intervene to thwart man's efforts in any given direction, it is quite within the bounds of reasonable expectation to be able to understand what these are, and how their effects are produced. An important consideration concerning the limitations of fish-culture must always be kept in mind in weighing the arguments for and against its success, viz., that effort towards the acclimatization of fishes in new waters is not fish-culture, but is simply one of the necessary experiments upon which fish-culture may be based. The introduction of carp from Germany to the United States was not fish-culture; it was an experiment; the experiment has succeeded, and fish-culture is now one of its results. The introduction of Californian salmon to the Atlantic slope was an experiment; it has not succeeded; its failure has nothing to do with the success of fish-culture. If any one wants to see successful fish-culture in connexion with this fish let him go to the Sacramento river. The introduction of shad to the Pacific coast was an experiment; it succeeded; shad culture can now be carried on without fear of failure by the Fish Commission of the Pacific States. An equally established success is whitefish culture in the Great Lakes. The experiments with cod and Spanish mackerel were not fish-culture, though it is hoped that they may yet lead up to it. And there is every reason to believe, from experiments in part completed, that the dominion of fish-culture may be extended in like manner to certain of the great sea fisheries, such as the cod, haddock, herring, mackerel, and Spanish mackerel fisheries.

¹ *Bulletin*, United States Fish Commission, 1883.

² *Transactions*, American Fish Cultural Association, 1883.

Public fish-culture exists only in the United States and Canada. European fish-culturists have always operated with only small numbers of eggs. The hatchery of Sir James Maitland at Howieton near Stirling, Scotland, may be specially mentioned in this connexion, since it is undoubtedly the finest private fish-cultural establishment in the world. It is described in one of the Conference papers of the International Fishery Exhibition.

The recent organization of the Scottish Fishery Board, and the establishment of a society for the biological investigation of the coasts of Great Britain, are indications that England, having at last recognized the importance of protecting its extensive fishery industries, will at no distant time become a leader in matters of fishery economy.

Holland, Germany, and Norway have hitherto been the only European nations manifesting intelligent enterprise in the consideration of fishery questions in general, although fair work has been done by Sweden and other countries in the treatment of limited special branches of this industry. In Germany the functions of the German Fishery Union (*Deutscher Fischerei-Verein*) and of the commission for the investigation of the German seas (*Ministerial-Kommission zur wissenschaftlichen Untersuchung der deutschen Meere zu Kiel*), taken together, represent practically the two divisions of the work of the United States Fish Commission, — propagation and investigation. The latter body is composed of a commission of scientific men, whose head is appointed by the Government; it is carried on with Government funds, but is not in any way subjected to Government control, the central headquarters being at Kiel instead of Berlin. The *Fischerei-Verein* is also a private body, under the patronage of the emperor, and with funds partly furnished by the Government and having also the general direction of the National Fish Cultural Society at Hünningen. This, also, is not a bureau of any Government department, but managed entirely by its own officers. It is the only European fisheries institution that has so far constituted a thoroughly successful experiment. The Netherlands Commission of Sea Fisheries (*Collegie voor de Zeevisserijen*) is a body of fifteen men, chiefly workers in science, occupying a responsible position in the national economy, their function being "to advise Government in all subjects connected with the interest of the fisheries." During the twenty-five years of its existence, says its historian, "the commission has constantly been consulted by Government on the different measures that might be beneficial, or on the abolition of others that were detrimental, to the fisheries." The Society for the Development of Norwegian Fisheries (*Selskabet for de Norske Fiskeriers Fremme*) is an organization independent of the Government, and electing its own officers, but receiving large grants from Government to carry on work precisely similar to that of the United States Commission. In 1882-83 these grants amounted to 49,000 kroner.

As an illustration of the interest manifested in fish-culture in the United States, it may be stated that from 1871 to 1883 \$1,190,955 has been appropriated by Congress for the use of the United States Fish Commission, and that thirty-five of the State Governments have made special grants for fish-culture, in the aggregate equal to \$1,101,000. To show the wholesale methods employed in this, a letter by Mr Livingston Stone, superintendent of one of the seventeen hatcheries supported by the United States Fish Commission, that on the M'Cloud river in California, may be quoted:—

"In the eleven years since the salmon-breeding station has been in operation 67,000,000 eggs have been taken, most of which have been distributed in the various States of the Union. Several millions, however, have been sent to foreign countries, including Germany, France, Great Britain, Denmark, Russia, Belgium, Holland, Canada, New Zealand, Australia, and the Sandwich Islands. About 15,000,000 have been hatched at the station, and the young fish placed in the M'Cloud and other tributaries of the Sacramento river. So great have been the benefits of this restocking of the Sacramento that the statistics of the salmon fisheries show that the annual salmon catch of the river has increased 5,000,000 pounds each year during the last few years."

Fifteen canneries now are fully supplied, whereas in 1872 the single establishment then on the river was obliged to close for lack of fish. In the two Government hatcheries at Alpena and Northville, Michigan, there have been produced in the winter of 1883-84 over 100,000,000 eggs of the whitefish, *Coregonus clupeaformis*, and the total number of young fish to be placed in the Great Lakes this year by these and the various State hatcheries will exceed 225,000,000. The fishermen of the Great Lakes admit that but for public fish-culture half of them would be obliged to abandon their calling. Instances of great improvement might be cited in connexion with nearly every shallow river in the United States. In the Potomac alone the annual yield has been brought up by the operations of fish-culture from 668,000 lb in 1877 to an average of more than 1,600,000 lb in recent years. In 1882 carp bred in the Fish Commission ponds in Washington were distributed in lots of 20 to 10,000 applicants throughout every State and Territory, at an average distance of more than 900 miles, the total mileage of the shipments being about 9,000,000 miles, and the actual distance traversed by the transportation car 34,000 miles. There still exists in Europe some scepticism as to the beneficial results of fish-culture. Such doubts do not exist on the other side of the Atlantic,

if the continuance from year to year of liberal grants of public money may be considered to be a test of public confidence.

Perhaps the best general treatises upon the methods of artificial propagation practised by pisciculturists are Herr Max Von Borne's *Fischzucht*, Berlin, 1880, and from the philosophical standpoint, Dr Francis Day's *Fish Culture*, one of the handbooks of the International Fisheries Exhibition of 1883. The reports and bulletins of the United States Fish Commission, in twelve volumes, from 1873 to 1884, contain full descriptions of American methods, and discussions of all foreign discoveries and movements. Two prominent London journals, the *Field* and *Land and Water*, contain authoritative articles upon the subject, and the museum of fisheries and fish-culture at South Kensington, enriched as it has been by the contributions of exhibitors at the Fisheries Exhibition of 1883, is an excellent exponent of the methods and implements in use in the past and at present. For a history of the subject see "Epochs in the History of Fish Culture," by G. Brown Goode, in *Transactions of the American Fish Cultural Association* (10th meeting, 1881, pp. 34-58), and "The Status of the United States Fish Commission in 1884," by the same author, in part xii. of the *Report of that commission*; and for a discussion of modern methods and apparatus, as shown at the late Fisheries Exhibition, the essays by Mr R. Edward Earl in the report of the United States commissioner to the exhibition and in *Nature* (Oct. 4, 1889). (G. B. G.)

PISEK, a small town of Bohemia, 55 miles to the south of Prague, lies on the right bank of the Wottawa, which is here crossed by an interesting stone bridge of great antiquity. The town generally has a mediæval air, heightened by the preservation of part of the old walls and bastions. The most prominent buildings are the church of the Nativity, the town-house, and the venerable chateau. The name of Pisek, which is the Czech for sand, is said to be derived from the gold-washing formerly carried on in the bed of the Wottawa. This source of profit, however, has been long extinct, and the inhabitants now support themselves by iron and brass founding, brewing, and the manufacture of shoes and Turkish fezes. The population in 1880 was 10,545.

Pisek was one of the chief centres of the Hussites, and it suffered very severely in the Thirty Years' War, when Maximilian of Bavaria put almost all the inhabitants to the sword. It was also occupied by the French in 1741. In spite of these reverses Pisek is now a very wealthy community, possessing large and valuable tracts of woodland.

PISIDIA, in ancient geography, was the name given to a country in the south of Asia Minor, immediately north of Pamphylia, by which it was separated from the Mediterranean, while it was bounded on the north by Phrygia, on the east by Isauria, Lycaonia, and Cilicia, and on the west and south-west by Lycia and a part of Phrygia (see vol. xv. Pl. II.). It was a rugged and mountainous district, comprising some of the loftiest portions of the great range of Mount Taurus, together with the offshoots of the same chain towards the central tableland of Phrygia. Such a region was naturally occupied from a very early period by wild and lawless races of mountaineers, who were very imperfectly reduced to subjection by the powers that successively established their dominion in Asia Minor. The Pisidians are not mentioned by Herodotus, either among the nations that were subdued by Cræsus, or among those that furnished contingents to the army of Xerxes, and the first mention of them in history occurs in the *Anabasis* of Xenophon, when they furnished a pretext to the younger Cyrus for levying the army with which he designed to subvert his brother's throne, while he pretended only to put down the Pisidians who were continually harassing the neighbouring nations by their lawless forays (*Anab.* i. 1, 11; ii. 1, 4, &c.). They are afterwards mentioned by Ephorus among the inland nations of Asia Minor, and assume a more prominent part in the history of Alexander the Great, to whose march through their country they opposed a determined resistance. In Strabo's time they had passed tranquilly under the Roman dominion, though still governed by their own petty chiefs and retaining to a considerable extent their predatory habits.

The boundaries of Pisidia, like those of most of the inland provinces or regions of Asia Minor, were not clearly defined, and appear to have fluctuated at different times. This was especially the case on the side of Lycia, where the upland district of Milyas was sometimes included in Pisidia, at other times assigned to Lycia. Some

writers, indeed, considered the Pisidians as the same people with the Milyans, while others regarded them as descendants of the Solymi, but Strabo speaks of the language of the Pisidians as distinct from that of the Solymi, as well as from that of the Lydians. The whole of Pisidia is an elevated region of tablelands or upland valleys in the midst of the ranges of Mount Taurus which descends abruptly on the side of Pamphylia. It contains several small lakes, but the only one of any importance is that now called the Egerdin Göl, of which the ancient name has not been preserved. It is a fresh-water lake of about 30 miles in length, situated in the north of Pisidia on the frontier of Phrygia, at an elevation of 2800 feet above the sea. The only rivers of any importance are the Cestrus and the Eurymedon, both of which take their rise in the highest ranges of Mount Taurus, and flow down through deep and narrow valleys to the plain of Pamphylia, which they traverse on their way to the sea.

Notwithstanding its rugged and mountainous character, Pisidia contained in ancient times several considerable towns, the ruins of which have been brought to light by the researches of recent travellers (Arundell, Hamilton, Daniell), and show them to have attained under the Roman empire to a degree of opulence and prosperity far beyond what we should have looked for in a country of predatory mountaineers. The most important of them are Termessus, near the frontier of Lycia, a strong fortress in a position of great natural strength and commanding one of the principal passes into Pamphylia; Cremna, another mountain fortress, north of the preceding, impeding over the valley of the Cestrus; Sagalassus, a little farther north, a large town in a strong position, the ruins of which are among the most remarkable in Asia Minor; Selge, on the right bank of the Eurymedon, surrounded by rugged mountains, notwithstanding which it was in Strabo's time a large and opulent city; and Antioch, known for distinction's sake as Antioch in Pisidia, and celebrated for the visit of St Paul. This was situated in the extreme north-east of the district immediately on the frontier of Phrygia, between Lake Egerdin and the range of the Sultan Dag. Besides these there were situated in the rugged mountain tract west of the Cestrus Cretopolis, Olba or Olbasa, Pogla, Isinda, Etenna, and Conana. Pednelissus was in the upper valley of the Eurymedon above Selge. The only place in the district at the present day deserving to be called a town is Isbarta, the residence of a pasha; it stands at the northern foot of Mount Taurus, looking over the great plain which extends from thence into Phrygia. North of this and immediately on the borders of Phrygia stood Apollonia, called also Mordæum. Several other towns are assigned to Pisidia by Strabo, Pliny, and Ptolemy, of which the sites have not yet been determined.

We have no clue to the ethnic character and relations of the Pisidians, except that we learn from Strabo that they were distinct from the neighbouring Solymi, who were probably a Semitic race, but we find mention at an early period in these mountain districts of various other tribes, as the Cabali, Milyans, &c., of all which, as well as the neighbouring Isaurians and Lycaonians, the origin is wholly unknown, and in the absence of monuments of their language must, in all probability, ever remain so.

PISISTRATUS, citizen and afterwards tyrant of Athens, was the son of Hippocrates, through whom he traced his pedigree to Neleus and Nestor, princes of Messene in the Heroic Age. A branch of the family had reigned at Athens in the persons of Codrus and his descendants. Pisistratus was second cousin to Solon, their mothers having been cousins, and the early friendship between the two men was not entirely broken off even by

the wide political differences which separated them in later life. Pisistratus, who was much junior to Solon, was born about 605 B.C. In his youth there was a keen rivalry between Athens and Megara, and Pisistratus as general of Athens contrived by stratagem to defeat the Megarians and capture their port Nisæa (perhaps 570 or a little later).¹ But Pisistratus was ambitious of more than military triumphs, and in the internal condition of Attica he discerned the road to power. The constitution which Solon had given to Athens a few years before (594 B.C.) was too moderate to satisfy either of the extreme parties. The wealthy nobles chafed at the political rights granted to the lower classes, while the poor were dissatisfied with what they regarded as merely a half measure of relief. The nobles themselves were divided into the parties known as the Plain (*Pediæis*) and the Coast (*Paraloi*), the former inhabiting the western lowlands of Attica, the latter the level districts on the southern and eastern coasts.² The former were led by the noble Lycurgus, the latter by Megacles, of the proud house of the Alcmaeonidæ. Pisistratus took advantage of their dissensions to form a third political party out of the men of the Mountain (*Diacreïs* or *Diacrioi*), the poor cottars and shepherds of the eastern and northern hills, among whom his own estates lay. He easily won the affection of these simple highlanders. His manners were captivating, his good humour imperturbable; his purse was ever at the service of the needy; his fields and gardens stood open for their enjoyment. Equality and fraternity, together with the maintenance of the constitution, were the watchwords of this eloquent and handsome aristocrat, the people's friend. But his easy and affable deportment hid a boundless ambition. Solon detected his schemes, and warned the people against him, but in vain. One day, not long after a violent dispute with Megacles in the public assembly, Pisistratus drove into the market-place, himself and his mules bleeding from wounds which he had inflicted with his own hand, but which he pretended to have received from his political enemies. The indignant people decreed a guard for the protection of their champion. Of this guard the champion soon availed himself in order to seize the Acropolis and make himself master of Athens (560). Megacles and the Alcmaeonidæ fled, but Solon remained and continued to lift his voice against the usurper, who, however, treated the old man with the utmost deference, as a valued friend and counsellor. Solon did not long survive his country's freedom; he died in the next year (559). The government of Pisistratus was marked by great moderation; he maintained the existing laws, to which he exacted obedience from all, and set the example of it himself. Being once accused of

¹ Herod., i. 59; Justin, ii. 8; Frontinus, iv. 7, 44. Other writers (Polyænus, i. 20; Ælian, *Var. Hist.*, vii. 19) erroneously attribute the stratagem to Solon, and refer it to the expedition in which Solon recovered Salamis. Plutarch (*Solon*, 8) falls into this mistake, and adds to it the blunder of representing Pisistratus as having taken part in the expedition, which happened about 600 B.C. The two events (Solon's conquest of Salamis and Pisistratus's capture of Salamis) are distinguished by Justin (ii. 7, 8), and after him by Duncker (*Gesch. des Alterthums*, vi. pp. 145, 244) and others, but they are confused by Thirlwall and Grote. From Plutarch (*Solon*, 8, 9) we may infer that the confusion arose in popular tradition. The account of the stratagem itself in the Greek writers Plutarch and Polyænus differs somewhat from that in the Latin writers Justin and Frontinus. Ælian follows (with some variations) the latter account.

² The difference between the *Pediæis* and the *Paraloi* seems to have been of the nature of a local feud between two ancient districts of Attica (Schol. on Aristoph., *Lys.*, 58; Strabo, ix. p. 392; Steph. Byz., s.v. *Διάκρια*, *Πάραλος*, *πεδῖον*; Suidas, s.v. *Πάραλοι*) rather than a disagreement between two political parties. It is true that Plutarch (*Solon*, 13) represents the *Paraloi* as a moderate political party, intermediate between the *Pediæis* (oligarchs) and the *Diacrioi* (democrats), but this has the appearance of being a mere conjecture of his own. His view is, however, accepted by Curtius and Duncker.

murder, he appeared in court like a private citizen to answer the charge, which, however, the accuser did not venture to press. But before he had time to establish himself firmly on the throne, he was expelled by a coalition of the Plain and Coast parties (perhaps in 555).¹ His property was confiscated and sold by auction. But after five or six years Megacles, unable to make head against the party of the Plain, proposed to Pisistratus to secure his recall on condition that Pisistratus should marry his daughter Cæsyra. Pisistratus agreed, and his return was effected by a stratagem. A tall and beautiful woman, Phya by name, was dressed as the goddess Athene, and drove into Athens on a chariot with Pisistratus at her side, while heralds proclaimed that Athene herself was bringing back Pisistratus. Thus restored, Pisistratus fulfilled his part of the bargain by marrying Cæsyra; but by his former marriage he had already sons approaching manhood (Hippias and Hipparchus), and he treated his young wife so slightly that Megacles, feeling himself affronted, made peace with his adversaries, and the united parties once more compelled Pisistratus to quit Athens (perhaps in 549). But he did not renounce his designs on the tyranny. The contributions which he received from various cities, especially Thebes, enabled him to hire a body of Argive mercenaries, with which he landed at Marathon in the eleventh year after his expulsion (perhaps in 538). His partisans flocked to him, and he defeated the Athenians at Pallene, and repossessed himself of the tyranny, which he thenceforward held till his death. He now placed his power on a securer basis by keeping a body of mercenaries in his pay, and levying a tax of a tenth or a twentieth on the produce of the soil. A further revenue accrued to him from the Thracian mines, and probably from the silver mines of Laurium, and the harbour and market dues. He now developed his plans for the extension of the naval empire of Athens in the Ægean. The island of Naxos was conquered by him, and handed over to Lygdamis, a native of the island, who had zealously supported the restoration of Pisistratus with men and money. In Naxos Pisistratus deposited the hostages he exacted from those of his enemies who chose to remain at Athens. In Sigeum on the Hellespont, which he conquered from the Mytilenians, he established as tyrant Hegesistratus, his son by an Argive wife, whom he had married in his second exile. The European side of the Hellespont was already in Athenian hands, Miltiades having established an Athenian colony on the Thracian Chersonese during the first tyranny, and with the consent of Pisistratus. Athens thus commanded the straits through which passed the corn trade of the Black Sea. Pisistratus further raised the reputation of Athens by purifying the sacred island of Delos; all the graves within sight of the temple of Apollo were opened and the dead removed to another part of the island. His rule was as wise and beneficent at home as it was glorious abroad. He encouraged agriculture by lending the poorer peasants cattle and seed, and he paid special attention to the cultivation of the olive. He enacted or enforced a law against idleness, and he required that the state should maintain its disabled soldiers. Under his rule and that of his sons Attica was intersected by high roads, which, converging to the capital, helped to unite the country and thus to abolish

local feuds and factions. To the tyrants Athens further owed those subterranean channels in the rock which still supply it with drinking water from the hills. Pisistratus also adorned Athens with splendid public buildings. The temple of the Pythian Apollo was his work; and he began, but did not finish, the great temple of Zeus, the remaining columns of which still astonish the beholder. Modern authorities² further ascribe to him the old Parthenon on the Acropolis, which was afterwards burned by the Persians and replaced by the Parthenon of Pericles. The Lyceum was attributed to him by Theopompus, but to Pericles by the better authority of Philochorus. He caused the Panathenaic festival to be celebrated every fourth year with unusual magnificence.

The well-known story that Pisistratus was the first to collect and publish the poems of Homer in their present form rests on the authority of late writers (Cicero being the earliest), and seems to be sufficiently disproved by the silence of all earlier authorities (see HOMER). The statement of Aulus Gellius that Pisistratus was the first to establish a public library at Athens is perhaps equally void of foundation. The tyrant seems to have been merciful and amiable to the last. It is not recorded of him that he ever put an enemy to death, and the easy good humour with which he submitted to affronts offered to himself and his family reminds us of Cæsar. Solon's description of him appears to have been justified—that apart from his ambition there was not a better-disposed man at Athens than Pisistratus. He died at an advanced age in 527, and was succeeded by his sons Hippias and Hipparchus (the Pisistratidæ), who continued to rule Athens in the same moderate and beneficent spirit.

(J. G. FR.)

PISTACHIO NUT, see NUT, vol. xvii. p. 665. The pistachio nut is the species named in Gen. xliii. 11 (Heb. *תִּשְׁתֵּי*, Ar. *botm*) as forming part of the present which Joseph's brethren took with them from Canaan, and in Egypt it is still often placed along with sweetmeats and the like in presents of courtesy. The nut is used in various ways; but the simplest plan is to boil it with salt.

PISTOIA, or PISTOJA, a well-walled ancient city, 21 miles north-west of Florence, on a slight eminence near the Ombrone, one of the tributaries of the Arno; it now contains about 12,500 inhabitants. The chief manufacture of the place is iron-working, especially fire-arms.³ It is on the site of the Roman *Pistoria*, of which little trace remains. During the Middle Ages Pistoia was at times a dangerous enemy to Florence, and the scene of constant conflicts between the Guelphs and the Ghibellines: it was there that, in the year 1300, the great party struggle took place which resulted in the creation of the Bianchi and Neri factions (see Dante, *Infer.*, xxiv., l. 121 to end). In the early development of architecture and sculpture Pistoia played a very important part; these arts, as they existed in Tuscany before the time of Niccola Pisano, can perhaps be better studied in Pistoia than anywhere else; nor is the city less rich in the later works produced by the school of sculptors founded by Niccola. In the 14th century Pistoia possessed a number of the most skilful artists in silver work, a wonderful specimen of whose powers exists now in the cathedral,—the great silver altar and frontal of St James, originally made for the high altar, but now placed in a chapel on the south side (see METAL WORK, vol. xvi. p. 65, fig. 4). The cathedral is partly of the 12th century, but rebuilt by one of the Pisani, and inside sadly modernized in the worst

¹ Out of the thirty-three years which elapsed between Pisistratus's first usurpation and his death in 527 B.C., we know (from Aristotle, *Pol.*, v. p. 1315 b) that he reigned during seventeen. He was twice deposed and banished, and his second exile lasted between ten and eleven years (Herod., i. 62); hence his first must have lasted between five and six. But we cannot fix with certainty the dates of these two exiles. Dunccker (with whom Clinton, *Fasti Hellenici*, ii. p. 254, and Stein on Herod., i. 64, nearly agree) places the first in 555–550, and the second in 549–538 (see his *Gesch. d. Alterthums*, vi. p. 454 sq.).

² Curtius and Dunccker in their histories of Greece; see also Wachsmuth, *Die Stadt Athen im Alterthum*, vol. i. p. 502.

³ The word "pistol" is derived (apparently through *pistolesco*, a dagger,—dagger and pistol being both small arms) from Pistoia, where that weapon was largely manufactured in the Middle Ages.

taste. Besides the silver altar it contains many fine works of sculpture; the chief are the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), and Verrocchio's finest work in marble, the monument to Cardinal Forteguerra (1474), with a large figure of Christ, surrounded by angels, in high relief. Unhappily two of the principal figures were destroyed not many years ago, and replaced by worthless modern ones.¹ Among the very early churches the principal is Sant' Andrea, enriched with sculpture, and probably designed, by Gruamons and his brother Adeodatus, in 1136; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches of almost equal interest are S. Giovanni Evangelista, also with sculpture by Gruamons, about 1160, and S. Bartolomeo in Pantano by the architect Rudolphus, 1167. S. Piero Maggiore and San Paolo are also churches begun in the 12th century. San Francesco al Prato is a fine church of the school of Niccolò Pisano, end of the 13th century. San Domenico, a noble church built about 1380, contains the beautiful tomb of Filippo Lazari by Bernardo di Matteo, 1464. In addition to its fine churches, of which the above is a very incomplete list, Pistoia contains many noble palaces and public buildings. The Palazzo del Commune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century domestic architecture, in very good preservation. The Ospedale del Ceppo, built originally in the 13th century, but remodelled in the 15th, is very remarkable for the reliefs in enamelled and coloured terra-cotta with which its exterior is richly decorated. Besides various medallions, there is a frieze of figures in high relief extending along the whole front, over its open arcade. The reliefs consist of a series of groups representing the Seven Works of Mercy and other figures; these were executed by the younger members of the Della Robbia family between 1525 and 1535, and, though not equal to the best work of Luca and Andrea, are yet very fine in conception and modelling, and extremely rich in their general decorative effect.

PITCAIRN, or PITCAIRN'S ISLAND, an island of the eastern Pacific, in 25°4' N. lat. and 130° 8' W. long., may be considered as a member or appendage of the Paumotu, Tuamotu, Low, or Dangerous Archipelago, but is nearly 100 miles south of Oeno. It is not more than 3 miles long from east to west and about 2 miles broad. Unlike the other islands of this region it has no coral reef, but rises abruptly from the depths with steep and rugged cliffs of dark basaltic lava. There is no anchorage except on a bank at the west end; and even the best of its three landing places—Bounty Bay on the north coast—is dangerous from the violence of the surf and the existence of a strong undertow. The longer axis of the island is formed by a range of steep hills, attaining in Outlook Ridge a maximum height of 1008 feet. On a plateau about 400 feet above the sea lies the village of Adamstown, with its fields and gardens. The climate is variable and rainy, and snow sometimes falls on the mountains; but, as there are no springs or streamlets, drinking water is apt to grow scarce in a dry season. Vegetation is luxuriant. Neither the bread fruit nor the cocoa nut, introduced by the settlers, are fully successful; but the sweet potato, which forms their staple food, banana, yam, taro, pineapple, &c., produce abundantly. Corn cannot be grown because of rats. The Pitcairn Islanders (not more than ninety in 1878), descended mainly from the mutineers of the "Bounty" and their Tahitian wives, are a healthy, virtuous, cheerful, and hospitable people, proud of their English

blood, and grateful for the services rendered them from time to time by the English Government and private liberality.

Stone axes, remains of sculptured stone pillars similar to those of Rapanui (Easter Island), and skeletons with a pearl-mussel beneath their head, have been found in the island, and show that, though it was uninhabited when discovered by Carteret in 1767, it had previously been occupied. Pitcairn was the name of the midshipman who first descried it from the mast-head. On 28th April 1789 a mutiny broke out on board the "Bounty," then employed by the English Government in conveying young bread-fruit trees from Tahiti to the West Indies. The commander, Lieutenant BLIGH (*q.v.*), was set adrift in the launch with a number of his officers and crew, but managed to make his way to Kupang in Timor (Dutch Indies). The mutineers, twenty-five in number, at first all returned to Tahiti. Of those who chose to be landed on that island, six were condemned to death by court-martial in England, and three of these were ultimately executed (1792). Two years earlier (1790) the other party (consisting of Fletcher Christian, the leader of the mutiny, eight other Englishmen, six Polynesian men, and twelve Polynesian women) had taken possession of Pitcairn and burned the "Bounty." The beautiful island, which might have been a paradise, was soon turned into a little hell. Treachery, drunkenness, madness, and murder fill the first years of its annals. By 1800 all the men were dead except Alexander Smith (afterwards known as John Adams), whose endeavours to train up the youthful generation thus left in his sole charge were crowned with success. An American vessel, the "Topaze," under Mayhew Folger, discovered the strange colony in 1808, and again, by accident, it was visited by the "Briton," Captain Sir F. Staines, and the "Tagus," Captain Pipon, in 1817. On the death of John Adams, 29th March 1829, George Hunn Nobbs, who, after an adventurous life had settled at Pitcairn in 1828, was appointed pastor and chief magistrate of the settlement. Through fear of drought the islanders, now numbering 87 persons, removed in 1830 to Tahiti, but neither the climate nor the morals of the place were such as they approved, and in 1831 they returned to their lonely island. Hardly had they settled into their old ways when Joshua Hill, a strange adventurer, rather crazy than criminal, appeared among them; claiming to be under Government authority, he tyrannized over them till his removal by an English man-of-war in 1838. In 1856 the whole population of Pitcairn—60 married persons and 134 young men, women, and children—were landed on NORFOLK ISLAND (*q.v.*); and the little island was again left to the occupancy of goats and cattle. In 1858, however, two men, William and Moses Young, chose to return with their families to their old homes, and their example was afterwards followed by a few others.

PITCAIRNE, ARCHIBALD (1652–1713), a distinguished Scottish physician, born at Edinburgh in 1652, and descended of an ancient Fifeshire family which barely escaped extinction at the battle of Flodden,—the proprietor of the estate and his seven sons having fallen in the battle, and the succession being only preserved by the birth of a posthumous child. After obtaining some classical education at the school of Dalkeith, Pitcairne entered Edinburgh university in 1668, and took his degree of M.A. in 1671. Like some men of great general ability, he seems to have remained long undetermined as to his future profession, and before taking to medicine he had made some progress first in divinity and then in law. But, having been sent to France for the benefit of his health, he was induced at Paris to begin the study of medicine. On his return to Scotland he applied himself for a time and with great success to the study of mathematics. Having at last taken vigorously to medicine, first at Edinburgh and afterwards for the second time at Paris, he obtained in 1680 his degree of M.D. from the faculty at Rheims. On returning to Scotland he at once began practice at Edinburgh, and in a short time acquired a great and wide reputation—so much so that in 1692 he was invited to fill a professor's chair at Leyden, and is said to have lectured there with great applause. Among his pupils were at least two men who afterwards rose to great eminence in their profession, Mead and Boerhaave, and both of them are understood to have attributed much of their skill to what they had learned from Pitcairne. In the following year

¹ One of the chief treasures of the S. Kensington Museum is the original sketch in clay for this monument, about 18 inches high,—now the only record of the original design of the two chief figures.

Pitcairne returned to Scotland to fulfil a matrimonial engagement with a daughter of Sir Archibald Stevenson, an eminent physician in Edinburgh; and, the family of the young lady having objected to their daughter going abroad, Pitcairne did not return to Leyden, but settled once more in Edinburgh, speedily acquired a most extensive practice, rose indeed to be the first physician of his time in Scotland, and was frequently called in as consulting physician not only in England but even in Holland.

Soon after his return to Edinburgh, feeling the great want of the means of anatomical study, he importuned the town council to permit himself and certain of his medical friends to dissect the bodies of paupers in "Paul's Work" unclaimed by their relations, and who therefore had hitherto been buried at the town's expense. They offered to attend them gratis when ill, and after dissection to bury them at their own charges. Strangely enough this proposal was strongly opposed by the chief surgeons of the place, but ultimately the town council had the good sense to comply with Pitcairne's request, and in this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine.

Though, according to Boerhaave, Pitcairne had not completely emancipated himself from some of the fanciful theories prevalent in his age in the science of medicine, yet the main characteristic of his superiority appears to have been that, like Sydenham and the higher class of physicians in England at that time, he insisted on strict adherence to the Baconian method of attending chiefly to facts of experience and observation. "Nothing," he remarks, "more hinders physic from being improved than the curiosity of searching into the natural causes of the effects of medicines. The business of men is to know the virtues of medicines, but to inquire whence they have that power is a superfluous amusement, since nature lies concealed. A physician ought therefore to apply himself to discover by experience the effects of medicines and diseases, and reduce his observations into maxims, and not needlessly fatigue himself by inquiring into their causes, which are neither possible nor necessary to be known. If all physicians would act thus we should not see physic divided into so many sects."

Pitcairne's medical opinions are chiefly contained in a volume of *Dissertations* which he published in 1701 (second and improved edition, 1713). In these he discusses the application of geometry to physic, the circulation of the blood in the smaller vessels, the difference in the quantity of the blood contained in the lungs of animals in the womb and of the same animals after birth, the motions by which food becomes fit to supply the blood, the question as to inventors in medicine (in which he repels the idea of certain medical discoveries of modern times having been known to the ancients, especially vindicating for Harvey the discovery of the circulation of the blood, and refuting the opinion of Dacier and others that it was known to Hippocrates), the cure of fevers by evacuating medicines, and the effects of acids and alkalis in medicine.

In addition to his great knowledge and skill as a physician, Pitcairne is understood to have been also an accomplished mathematician. He was intimate with the two Gregorys, and is said to have made some improvement on the method of infinite series invented by David Gregory. His strong addiction to mathematics seems to have misled him, along with some other eminent men of his time, into the idea of applying its methods of reasoning to subjects for which they are quite unfitted: in Pitcairne's case the attempt is made in one of his papers to adapt them to medicine.

He was also a very thorough classical scholar, and wrote

Latin verses, occasionally with something more than mere imitative cleverness and skill. Some verses of his on the death of Lord Dundee were translated by Dryden, and, as one of the latest editors of Dryden's poetry with perfect justice remarks, "the translation will not be thought so happy as the original."

According to the representations which are left by his contemporaries of his personal bearing and character, he seems to have carried his great faculties very lightly. A strong man all round, with great animal spirits and jovial habits, somewhat contemptuous of the gravities and feeblosities around him, a loudly avowed Jacobite and Episcopalian, rather reckless in his jests and sarcasms, and spending a good deal of his time in clubs, public houses, and drinking jollities, he was evidently regarded with little favour and some suspicion by the sober and decent Presbyterian circles of Edinburgh. "Drunk twice a day," according to the worthy, credulous, gossiping Wodrow (in one of his note books); "an unbeliever," "much given to profane jests," an "atheist," according to others. These reports may be taken for what they are worth, which perhaps is not very much. What is certain is that he was repeatedly involved in violent quarrels with his medical brethren and others, and once or twice got into scrapes with the Government on account of his indiscreet political utterances. Among his friends, however, he was evidently well liked, and he is known to have acted with great kindness and generosity to deserving men who needed his help. Ruddiman, the great Scottish scholar, for example, was rescued from a life of obscurity by his encouragement and assistance, and by no one was his memory more gratefully cherished.

"—Vale, lux Scotigenum, princepsque Medentum,
Musarum column deliciaeque, vale!"

are the concluding lines of a Latin epitaph by him on his venerated patron and friend, which still remains on Pitcairne's monument in the Greyfriars churchyard. Mead too, appears never to have forgotten what he owed to his old teacher at Leyden. A son of Pitcairne's had gone out in the rebellion of 1715, and, having been condemned to death was saved by the earnest interposition of Mead with Sir Robert Walpole. He pleaded, very artfully, that if Walpole's health had been bettered by his skill, or if members of the royal family were preserved by his care, it was owing to the instruction he had received from Dr Pitcairne. Pitcairne died in October 1713. Among his other scholarly tastes he had been a great collector of books, and his library, which is understood to have been of considerable value, was, through the influence of Ruddiman, disposed of to Peter the Great of Russia.

PITCHER PLANTS. See INSECTIVOROUS PLANTS, vol. xiii. pp. 138, 139.

PITHOM, a city of Egypt, mentioned in Exod. i. 11, along with RAMESES (*q.v.*).

PITHOU, PIERRE (1539–1596), lawyer and scholar, was born at Troyes on November 1, 1539. His taste for literature was early seen, and his father, an advocate, cultivated it to the utmost. He first studied at Troyes, and afterwards went to Paris, where he completed his classical studies under Adrien Turnèbe and Pierre Galand. He next attended the lectures in law of Cujas at Bourges and Valence, and was called to the Paris bar in 1560. Here he achieved but little success as a pleader, but soon acquired a considerable practice as a consulting lawyer. On the outbreak of the second war of religion in 1567, Pithou, who was a Calvinist, withdrew to Sedan and afterwards to Basel, whence he returned to France on the publication of the edict of pacification. Soon afterwards he accompanied the

Duc de Montmorency on his embassy to England, returning shortly before the massacre of St Bartholomew, in which he narrowly escaped with his life. Next year he followed the example of Henry of Navarre, to whose cause he was ardently attached, by abjuring the Protestant faith. Henry, shortly after his own accession to the throne of France, recognized Pithou's talents and services by bestowing upon him various legal appointments. It was considerably after this date that Pithou achieved what was probably the most important work of his life, whether political or literary, by co-operating in the production of the powerful *Satire Menippée* (1593), which did so much to damage the cause of the League; the harangue of Daubray is usually attributed to his pen. He died at Nogent-sur-Seine on November 1, 1596. His valuable library, specially rich in MSS., was for the most part transferred to what is now the Bibliothèque Nationale in Paris.

Pithou wrote a great number of legal and historical books, besides preparing editions of several ancient authors. His earliest publication was *Adversariorum Subsecutorum Lib. II.* (1565), which was highly praised by Turnèbe, Lipsius, and others. Perhaps his edition of the *Leges Visigothorum* (1579) was his most valuable contribution to historical science; in the same line he edited the *Capitula* of Charlemagne, Louis the Pious, and Charles the Bald in 1588, and he also assisted his brother François in preparing an edition of the *Corpus Juris Canonici* (1687). His essay *On the Gallican Liberties* (1594) is reprinted in his *Opera sacra juridica historica miscellanea collecta* (1609). In classical literature he was the first who made the world acquainted with the *Fables* of Phædrus (1596); he also edited the *Pervigilium Veneris* (1587), and Juvenal and Persius (1585).

PITT, WILLIAM, FIRST EARL OF CHATHAM. See CHATHAM.

Born at
Hayes,
near
Bromley,
Kent,
May 28,
1759.

PITT, WILLIAM (1759–1806), the second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, daughter of Hester, Countess Temple, was born on the 28th of May 1759. The child inherited a name which, at the time of his birth, was the most illustrious in the civilized world, and was pronounced by every Englishman with pride, and by every enemy of England with mingled admiration and terror. During the first year of his life every month had its illuminations and bonfires, and every wind brought some messenger charged with joyful tidings and hostile standards. In Westphalia the English infantry won a great battle which arrested the armies of Louis XV. in the midst of a career of conquest; Boscawen defeated one French fleet on the coast of Portugal; Hawke put to flight another in the Bay of Biscay; Johnson took Niagara; Amherst took Ticonderoga; Wolfe died by the most enviable of deaths under the walls of Quebec; Clive destroyed a Dutch armament in the Hooghly, and established the English supremacy in Bengal; Coote routed Lally at Wandewash, and established the English supremacy in the Carnatic. The nation, while loudly applauding the successful warriors, considered them all, on sea and on land, in Europe, in America, and in Asia, merely as instruments which received their direction from one superior mind. It was the great William Pitt, the great commoner, who had vanquished the French marshals in Germany and French admirals on the Atlantic,—who had conquered for his country one great empire on the frozen shores of Ontario and another under the tropical sun near the mouths of the Ganges. It was not in the nature of things that popularity such as he at this time enjoyed should be permanent. That popularity had lost its gloss before his children were old enough to understand that their father was a great man. He was at length placed in situations in which neither his talents for administration nor his talents for debate appeared to the best advantage. The energy and decision which had eminently fitted him for the direction of war were not needed in time of peace. The lofty and spirit-stirring

eloquence which had made him supreme in the House of Commons often fell dead on the House of Lords. A cruel malady racked his joints, and left his joints only to fall on his nerves and on his brain. During the closing years of his life he was odious to the court, and yet was not on cordial terms with the great body of the Opposition. Chatham was only the ruin of Pitt, but an awful and majestic ruin, not to be contemplated by any man of sense and feeling without emotions resembling those which are excited by the remains of the Parthenon and of the Colosseum. In one respect the old statesman was eminently happy. Whatever might be the vicissitudes of his public life, he never failed to find peace and love by his own hearth. He loved all his children, and was loved by them; and of all his children the one of whom he was fondest and proudest was his second son.

The child's genius and ambition displayed themselves ^{Child.} with a rare and almost unnatural precocity. At seven the hood. interest which he took in grave subjects, the ardour with which he pursued his studies, and the sense and vivacity of his remarks on books and on events amazed his parents and instructors. One of his sayings of this date was reported to his mother by his tutor. In August 1766, when the world was agitated by the news that Mr Pitt had become earl of Chatham, little William exclaimed, "I am glad that I am not the eldest son. I want to speak in the House of Commons like papa." A letter is extant in which Lady Chatham, a woman of considerable abilities, remarked to her lord that their younger son at twelve had left far behind him his elder brother, who was fifteen. "The fineness," she wrote, "of William's mind makes him enjoy with the greatest pleasure what would be above the reach of any other creature of his small age." At fourteen the lad was in intellect a man. Hayley, who met him at Lyme in the summer of 1773, was astonished, delighted, and somewhat overawed, by hearing wit and wisdom from so young a mouth. The poet, indeed, was afterwards sorry that his shyness had prevented him from submitting the plan of an extensive literary work, which he was then meditating, to the judgment of this extraordinary boy. The boy, indeed, had already written a tragedy, bad, of course, but not worse than the tragedies of his friend. This piece is still preserved at Chevening, and is in some respects highly curious. There is no love. The whole plot is political; and it is remarkable that the interest, such as it is, turns on a contest about a regency. On one side is a faithful servant of the crown, on the other an ambitious and unprincipled conspirator. At length the king, who had been missing, reappears, resumes his power, and rewards the faithful defender of his rights. A reader who should judge only by internal evidence would have no hesitation in pronouncing that the play was written by some Pittite poetaster at the time of the rejoicings for the recovery of George III. in 1789.

The pleasure with which William's parents observed the ^{Educa-} rapid development of his intellectual powers was alloyed by tion. apprehensions about his health. He shot up alarmingly fast; he was often ill, and always weak; and it was feared that it would be impossible to rear a stripling so tall, so slender, and so feeble. Port wine was prescribed by his medical advisers; and it is said that he was, at fourteen, accustomed to take this agreeable physic in quantities which would, in our abstemious age, be thought much more than sufficient for any full-grown man. This regimen, though it would probably have killed ninety-nine boys out of a hundred, seems to have been well suited to the peculiarities of William's constitution; for at fifteen he ceased to be molested by disease, and, though never a strong man, continued, during many years of labour and anxiety, of nights passed in debate and of summers passed in London,

to be a tolerably healthy one. It was probably on account of the delicacy of his frame that he was not educated like other boys of the same rank. Almost all the eminent English statesmen and orators to whom he was afterwards opposed or allied—North, Fox, Shelburne, Windham, Grey, Wellesley, Grenville, Sheridan, Canning—went through the training of great public schools. Lord Chatham had himself been a distinguished Etonian; and it is seldom that a distinguished Etonian forgets his obligations to Eton. But William's infirmities required a vigilance and tenderness such as could be found only at home. He was therefore bred under the paternal roof. His studies were superintended by a clergyman named Wilson; and those studies, though often interrupted by illness, were prosecuted with extraordinary success. Before the lad had completed his fifteenth year his knowledge both of the ancient languages and of mathematics was such as very few men of eighteen then carried up to college. He was therefore sent, towards the close of the year 1773, to Pembroke Hall, in the university of Cambridge. So young a student required much more than the ordinary care which a college tutor bestows on undergraduates. The governor to whom the direction of William's academical life was confided was a bachelor of arts named Pretzman,¹ who had been senior wrangler in the preceding year, and who, though not a man of prepossessing appearance or brilliant parts, was eminently acute and laborious, a sound scholar, and an excellent geometrician. At Cambridge Pretzman was, during more than two years, the inseparable companion, and indeed almost the only companion, of his pupil. A close and lasting friendship sprang up between the pair. The disciple was able, before he completed his twenty-eighth year, to make his preceptor bishop of Lincoln and dean of St Paul's; and the preceptor showed his gratitude by writing a life of the disciple, which enjoys the distinction of being the worst biographical work of its size in the world.

Pitt, till he graduated, had scarcely one acquaintance, attended chapel regularly morning and evening, dined every day in hall, and never went to a single evening party. At seventeen he was admitted, after the bad fashion of those times, by right of birth, without any examination, to the degree of master of arts. But he continued during some years to reside at college, and to apply himself vigorously, under Pretzman's direction, to the studies of the place, while mixing freely in the best academic society.

The stock of learning which Pitt laid in during this part of his life was certainly very extraordinary. In fact, it was all that he ever possessed; for he very early became too busy to have any spare time for books. The work in which he took the greatest delight was Newton's *Principia*. His liking for mathematics, indeed, amounted to a passion, which, in the opinion of his instructors, themselves distinguished mathematicians, required to be checked rather than encouraged. The acuteness and readiness with which he solved problems was pronounced by one of the ablest of the moderators, who in those days presided over the disquisitions in the schools and conducted the examinations of the senate-house, to be unrivalled in the university. Nor was the youth's proficiency in classical learning less remarkable. In one respect, indeed, he appeared to disadvantage when compared with even second-rate and third-rate men from public schools. He had never, while under Wilson's care, been in the habit of composing in the ancient languages; and he therefore never acquired that knack of

versification which is sometimes possessed by clever boys whose knowledge of the language and literature of Greece and Rome is very superficial. It would have been utterly out of his power to produce such charming elegiac lines as those in which Wellesley bade farewell to Eton, or such Virgilian hexameters as those in which Canning described the pilgrimage to Mecca. But it may be doubted whether any scholar has ever, at twenty, had a more solid and profound knowledge of the two great tongues of the old civilized world. The facility with which he penetrated the meaning of the most intricate sentences in the Attic writers astonished veteran critics. He had set his heart on being intimately acquainted with all the extant poetry of Greece, and was not satisfied till he had mastered Lycophron's *Cassandra*, the most obscure work in the whole range of ancient literature. This strange rhapsody, the difficulties of which have perplexed and repelled many excellent scholars, "he read," says his preceptor, "with an ease at first sight which, if I had not witnessed it, I should have thought beyond the compass of human intellect."

To modern literature Pitt paid comparatively little attention. He knew no living language except French; and French he knew very imperfectly. With a few of the best English writers he was intimate, particularly with Shakspeare and Milton. The debate in Pandemonium was, as it well deserved to be, one of his favourite passages; and his early friends used to talk, long after his death, of the just emphasis and the melodious cadence with which they had heard him recite the incomparable speech of Belial. He had indeed been carefully trained from infancy in the art of managing his voice, a voice naturally clear and deep-toned. His father, whose oratory owed no small part of its effect to that art, had been a most skilful and judicious instructor. At a later period the wits of Brookes's, irritated by observing, night after night, how powerfully Pitt's sonorous elocution fascinated the rows of country gentlemen, reproached him with having been "taught by his dad on a stool."

His education, indeed, was well adapted to form a great parliamentary speaker. One argument often urged against those classical studies which occupy so large a part of the early life of every gentleman bred in the south of our island is, that they prevent him from acquiring a command of his mother tongue, and that it is not unusual to meet with a youth of excellent parts, who writes Ciceronian Latin prose and Horatian Latin alcaics, but who would find it impossible to express his thoughts in pure, perspicuous, and forcible English. There may perhaps be some truth in this observation. But the classical studies of Pitt were carried on in a peculiar manner, and had the effect of enriching his English vocabulary, and of making him wonderfully expert in the art of constructing correct English sentences. His practice was to look over a page or two of a Greek or Latin author, to make himself master of the meaning, and then to read the passage straight forward into his own language. This practice, begun under his first teacher Wilson, was continued under Pretzman. It is not strange that a young man of great abilities, who had been exercised daily in this way during ten years, should have acquired an almost unrivalled power of putting his thoughts, without premeditation, into words well selected and well arranged.

Of all the remains of antiquity, the orations were those on which he bestowed the most minute examination. His favourite employment was to compare harangues on opposite sides of the same question, to analyse them, and to observe which of the arguments of the first speaker were refuted by the second, which were evaded, and which were left untouched. Nor was it only in books that he at this time studied the art of parliamentary fencing. When he

¹ George Pretzman (1750–1827) was senior wrangler in 1772. In 1803, on falling heir to a large estate, he assumed the name of Tomline. From Lincoln, to which see he had been elevated in 1787, he was translated to Winchester in 1820. Tomline, to whom Pitt when dying had bequeathed his papers, published his *Memoirs of the Life of William Pitt* (down to the close of 1792) in 1821 (3 vols. 8vo.)]

was at home, he had frequent opportunities of hearing important debates at Westminster; and he heard them, not only with interest and enjoyment, but with a close scientific attention resembling that with which a diligent pupil at Guy's Hospital watches every turn of the hand of a great surgeon through a difficult operation. On one of these occasions Pitt, a youth whose abilities were as yet known only to his own family and to a small knot of college friends, was introduced on the steps of the throne in the House of Lords to Fox, who was his senior by eleven years, and who was already the greatest debater, and one of the greatest orators, that had appeared in England. Fox used afterwards to relate that, as the discussion proceeded, Pitt repeatedly turned to him, and said, "But surely, Mr Fox, that might be met thus;" or "Yes; but he lays himself open to this retort." What the particular criticisms were Fox had forgotten; but he said that he was much struck at the time by the precocity of a lad who, through the whole sitting, seemed to be thinking only how all the speeches on both sides could be answered.

One of the young man's visits to the House of Lords was a sad and memorable era in his life. He had not quite completed his nineteenth year when, on the 7th of April 1778, he attended his father to Westminster. A great debate was expected. It was known that France had recognized the independence of the United States. The duke of Richmond was about to declare his opinion that all thought of subjugating those states ought to be relinquished. Chatham had always maintained that the resistance of the colonies to the mother country was justifiable. But he conceived, very erroneously, that on the day on which their independence should be acknowledged the greatness of England would be at an end. Though sinking under the weight of years and infirmities, he determined, in spite of the entreaties of his family, to be in his place. His son supported him to a seat. The excitement and exertion were too much for the old man. In the very act of addressing the peers, he fell back in convulsions. A few weeks later his corpse was borne, with gloomy pomp, from the Painted Chamber to the Abbey. The favourite child and namesake of the deceased statesman followed the coffin as chief mourner, and saw it deposited in the transept where his own was destined to lie.

His elder brother, now earl of Chatham, had means sufficient, and barely sufficient, to support the dignity of the peerage. The other members of the family were poorly provided for. William had little more than three hundred a year. It was necessary for him to follow a profession. He had already begun to eat his terms. In the spring of 1780 he came of age. He then quitted Cambridge, was called to the bar, took chambers in Lincoln's Inn, and joined the western circuit. In the autumn of that year a general election took place; and he offered himself as a candidate for the university; but he was at the bottom of the poll. It is said that the grave doctors who then sat, robed in scarlet, on the benches of Golgotha thought it great presumption in so young a man to solicit so high a distinction. He was, however, at the request of a hereditary friend, the duke of Rutland, brought into parliament by Sir James Lowther for the

borough of Appleby. The dangers of the country were at that time such as might well have disturbed even a constant mind. Army after army had been sent in vain against the rebellious colonists of North America. On pitched fields of battle the advantage had been with the disciplined troops of the mother country. But it was not on pitched fields of battle that the event of such a contest could be decided. An armed nation, with hunger and the Atlantic for auxiliaries,

was not to be subjugated. Meanwhile the house of Bourbon, humbled to the dust a few years before by the genius and vigour of Chatham, had seized the opportunity of revenge. France and Spain had united against us, and had recently been joined by Holland. The command of the Mediterranean had been for a time lost. The British flag had been scarcely able to maintain itself in the British Channel. The northern powers professed neutrality; but their neutrality had a menacing aspect. In the East, Hyder had descended on the Carnatic, had destroyed the little army of Baillie, and had spread terror even to the ramparts of Fort St George. The discontents of Ireland threatened nothing less than civil war. In England the authority of the Government had sunk to the lowest point. The king and the House of Commons were alike unpopular. The cry for parliamentary reform was scarcely less loud and vehement than in the autumn of 1830. Formidable associations, headed, not by ordinary demagogues, but by men of high rank, stainless character, and distinguished ability, demanded a revision of the representative system. The populace, emboldened by the impotence and irresolution of the Government, had recently broken loose from all restraint, besieged the chambers of the legislature, hustled peers, hunted bishops, attacked the residences of ambassadors, opened prisons, burned and pulled down houses. London had presented during some days the aspect of a city taken by storm; and it had been necessary to form a camp among the trees of St James's Park.

In spite of dangers and difficulties abroad and at home, George III., with a firmness which had little affinity with virtue or with wisdom, persisted in his determination to put down the American rebels by force of arms; and his ministers submitted their judgment to his. Some of them were probably actuated merely by selfish cupidity; but their chief, Lord North, a man of high honour, amiable temper, winning manners, lively wit, and excellent talents both for business and for debate, must be acquitted of all sordid motives. He remained at a post from which he had long wished and had repeatedly tried to escape, only because he had not sufficient fortitude to resist the entreaties and reproaches of the king, who silenced all arguments by passionately asking whether any gentleman, any man of spirit, could have the heart to desert a kind master in the hour of extremity.

The Opposition consisted of two parties which had once been hostile to each other, and which had been very slowly and, as it soon appeared, very imperfectly reconciled, but which at this conjuncture seemed to act together with cordiality. The larger of these parties consisted of the great body of the Whig aristocracy. Its head was Charles, marquis of Rockingham, a man of sense and virtue, and in wealth and parliamentary interest equalled by very few of the English nobles, but afflicted with a nervous timidity which prevented him from taking a prominent part in debate. In the House of Commons the adherents of Rockingham were led by Fox, whose dissipated habits and ruined fortunes were the talk of the whole town, but whose commanding genius, and whose sweet, generous, and affectionate disposition, extorted the admiration and love of those who most lamented the errors of his private life. Burke, superior to Fox in largeness of comprehension, in extent of knowledge, and in splendour of imagination, but less skilled in that kind of logic and in that kind of rhetoric which convince and persuade great assemblies, was willing to be the lieutenant of a young chief who might have been his son.

A smaller section of the Opposition was composed of the old followers of Chatham. At their head was William, earl of Shelburne, distinguished both as a statesman and

as a lover of science and letters. With him were leagued Lord Camden, who had formerly held the great seal, and whose integrity, ability, and constitutional knowledge commanded the public respect; Barré, an eloquent and acrimonious declaimer; and Dunning, who had long held the first place at the English bar. It was to this party that Pitt was naturally attracted.

On the 26th of February 1781 he made his first speech in favour of Burke's plan of economical reform. Fox stood up at the same moment, but instantly gave way. The lofty yet animated deportment of the young member, his perfect self-possession, the readiness with which he replied to the orators who had preceded him, the silver tones of his voice, the perfect structure of his unpremeditated sentences, astonished and delighted his hearers. Burke, moved even to tears, exclaimed, "It is not a chip of the old block; it is the old block itself." "Pitt will be one of the first men in parliament," said a member of the opposition to Fox. "He is so already," answered Fox, in whose nature envy had no place. It is a curious fact, well remembered by some who were very recently living,¹ that soon after this debate Pitt's name was put up by Fox at Brookes's.

On two subsequent occasions during that session Pitt addressed the House, and on both fully sustained the reputation which he had acquired on his first appearance. In the summer, after the prorogation, he again went the western circuit, held several briefs, and acquitted himself in such a manner that he was highly complimented by Buller from the bench, and by Dunning at the bar.

On the 27th of November the parliament reassembled. Only forty-eight hours before had arrived tidings of the surrender of Cornwallis and his army; and it had consequently been necessary to rewrite the royal speech. Every man in the kingdom, except the king, was now convinced that it was mere madness to think of conquering the United States. In the debate on the report of the address, Pitt spoke with even more energy and brilliancy than on any former occasion. He was warmly applauded by his allies; but it was remarked that no person on his own side of the house was so loud in eulogy as Henry Dundas, the lord advocate of Scotland, who spoke from the ministerial ranks. That able and versatile politician distinctly foresaw the approaching downfall of the Government with which he was connected, and was preparing to make his own escape from the ruin. From that night dates his connexion with Pitt, a connexion which soon became a close intimacy, and which lasted till it was dissolved by death.

About a fortnight later Pitt spoke in the committee of supply on the army estimates. Symptoms of dissension had begun to appear on the treasury bench. Lord George Germaine, the secretary of state who was especially charged with the direction of the war in America, had held language not easily to be reconciled with declarations made by the first lord of the treasury. Pitt noticed the discrepancy with much force and keenness. Lord George and Lord North began to whisper together; and Welbore Ellis, an ancient placeman who had been drawing salary almost every quarter since the days of Henry Pelham, bent down between them to put in a word. Such interruptions sometimes discompose veteran speakers. Pitt stopped, and, looking at the group, said, with admirable readiness, "I shall wait till Nestor has composed the dispute between Agamemnon and Achilles."

After several defeats, or victories hardly to be distinguished from defeats, the ministry resigned. The king, reluctantly and ungraciously, consented to accept Rock-

ingham as first minister. Fox and Shelburne became secretaries of state. Lord John Cavendish, one of the most upright and honourable of men, was made chancellor of the exchequer. Thurlow, whose abilities and force of character had made him the dictator of the House of Lords, continued to hold the great seal.

To Pitt was offered, through Shelburne, the vice-treasurership of Ireland, one of the easiest and most highly paid places in the gift of the crown; but the offer was without hesitation declined. The young statesman had resolved to accept no post which did not entitle him to a seat in the cabinet; and a few days later he announced that resolution in the House of Commons. It must be remembered that the cabinet was then a much smaller and more select body than at present. We have seen cabinets of sixteen. In the time of our grandfathers a cabinet of ten or eleven was thought inconveniently large. Seven was a usual number. Even Burke, who had taken the lucrative office of paymaster, was not in the cabinet. Many therefore thought Pitt's declaration indecent. He himself was sorry that he had made it. The words, he said in private, had escaped him in the heat of speaking; and he had no sooner uttered them than he would have given the world to recall them. They, however, did him no harm with the public. The second William Pitt, it was said, had shown that he had inherited the spirit as well as the genius of the first. In the son, as in the father, there might perhaps be too much pride; but there was nothing low or sordid. It might be called arrogance in a young barrister, living in chambers on three hundred a year, to refuse a salary of five thousand a year, merely because he did not choose to bind himself to speak or vote for plans which he had no share in framing; but surely such arrogance was not very far removed from virtue.

Pitt gave a general support to the administration of Rockingham, but omitted, in the meantime, no opportunity of courting that ultra-Whig party which the persecution of Wilkes and the Middlesex election had called into existence, and which the disastrous events of the war, and the triumph of republican principles in America, had made formidable both in numbers and in temper. He supported a motion for shortening the duration of parliaments. He made a motion for a committee to examine into the state of the representation, and, in the speech by which that motion was introduced, avowed himself the enemy of the close boroughs, the strongholds of that corruption to which he attributed all the calamities of the nation, and which, as he phrased it in one of those exact and sonorous sentences of which he had a boundless command, had grown with the growth of England and strengthened with her strength, but had not diminished with her diminution or decayed with her decay. On this occasion he was supported by Fox. The motion was lost by only twenty votes in a house of more than three hundred members. The reformers never again had so good a division till the year 1831.

The new administration was strong in abilities, and was more popular than any administration which had held office since the first year of George III., but was hated by the king, hesitatingly supported by the Parliament, and torn by internal dissensions. The chancellor was disliked and distrusted by almost all his colleagues. The two secretaries of state regarded each other with no friendly feeling. The line between their departments had not been traced with precision; and there were consequently jealousies, encroachments, and complaints. It was all that Rockingham could do to keep the peace in his cabinet; and before the cabinet had existed three months Rockingham died.

In an instant all was confusion. The adherents of the

Shelburne ministry.

Pitt chancellor of the exchequer, July 1782.

deceased statesman looked on the duke of Portland as their chief. The king placed Shelburne at the head of the treasury. Fox, Lord John Cavendish, and Burke immediately resigned their offices; and the new prime minister was left to constitute a Government out of very defective materials. His own parliamentary talents were great; but he could not be in the place where parliamentary talents were most needed. It was necessary to find some member of the House of Commons who could confront the great orators of the Opposition; and Pitt alone had the eloquence and the courage which were required. He was offered the great place of chancellor of the exchequer, and he accepted it. He had scarcely completed his twenty-third year.

The parliament was speedily prorogued. During the recess a negotiation for peace which had been commenced under Rockingham was brought to a successful termination. England acknowledged the independence of her revolted colonies; and she ceded to her European enemies some places in the Mediterranean and in the Gulf of Mexico. But the terms which she obtained were quite as advantageous and honourable as the events of the war entitled her to expect, or as she was likely to obtain by persevering in a contest against immense odds. All her vital parts, all the real sources of her power, remained uninjured. She preserved even her dignity; for she ceded to the house of Bourbon only part of what she had won from that house in previous wars. She retained her Indian empire undiminished; and, in spite of the mightiest efforts of two great monarchies, her flag still waved on the rock of Gibraltar. There is not the slightest reason to believe that Fox, if he had remained in office, would have hesitated one moment about concluding a treaty on such conditions. Unhappily that great and most amiable man was, at this crisis, hurried by his passions into an error which made his genius and his virtues, during a long course of years, almost useless to his country.

He saw that the great body of the House of Commons was divided into three parties—his own, that of North, and that of Shelburne; that none of those three parties was large enough to stand alone; that, therefore, unless two of them united there must be a miserably feeble administration, or, more probably, a rapid succession of miserably feeble administrations, and this at a time when a strong Government was essential to the prosperity and respectability of the nation. It was then necessary and right that there should be a coalition. To every possible coalition there were objections. But of all possible coalitions that to which there were the fewest objections was undoubtedly a coalition between Shelburne and Fox. It would have been generally applauded by the followers of both. It might have been made without any sacrifice of public principle on the part of either. Unhappily, recent bickerings had left in the mind of Fox a profound dislike and distrust of Shelburne. Pitt attempted to mediate, and was authorized to invite Fox to return to the service of the crown. "Is Lord Shelburne," said Fox, "to remain prime minister?" Pitt answered in the affirmative. "It is impossible that I can act under him," said Fox. "Then negotiation is at an end," said Pitt; "for I cannot betray him." Thus the two statesmen parted. They were never again in a private room together.

As Fox and his friends would not treat with Shelburne, nothing remained to them but to treat with North. That fatal coalition which is emphatically called "The Coalition", was formed. Not three quarters of a year had elapsed since Fox and Burke had threatened North with impeachment, and had described him night after night as the most arbitrary, the most corrupt, and the most incapable of ministers. They now allied themselves with him

for the purpose of driving from office a statesman with whom they cannot be said to have differed as to any important question. Nor had they even the prudence and the patience to wait for some occasion on which they might, without inconsistency, have combined with their old enemies in opposition to the Government. That nothing might be wanting to the scandal of the great orators who had, during seven years, thundered against the war determined to join with the authors of that war in passing a vote of censure on the peace.

The parliament met before Christmas 1782. But it was not till January 1783 that the preliminary treaties 1783 were signed. On the 17th of February they were taken into consideration by the House of Commons. There had been, during some days, floating rumours that Fox and North had coalesced; and the debate indicated but too clearly that those rumours were not unfounded. Pitt was suffering from indisposition; he did not rise till his own strength and that of his hearers were exhausted; and he was consequently less successful than on any former occasion. His admirers owned that his speech was feeble and petulant. He so far forgot himself as to advise Sheridan to confine himself to amusing theatrical audiences. This ignoble sarcasm gave Sheridan an opportunity of retorting with great felicity. "After what I have seen and heard to-night," he said, "I really feel strongly tempted to venture on a competition with so great an artist as Ben Jonson, and to bring on the stage a second *Angry Boy*." On a division, the address proposed by the supporters of the Government was rejected by a majority of sixteen.

But Pitt was not a man to be disheartened by a single failure, or to be put down by the most lively repartee. When, a few days later, the Opposition proposed a resolution directly censuring the treaties, he spoke with an eloquence, energy, and dignity which raised his fame and popularity higher than ever. To the coalition of Fox and North he alluded in language which drew forth tumultuous applause from his followers. "If," he said, "this ill-omened and unnatural marriage be not yet consummated, I know of a just and lawful impediment; and, in the name of the public weal, I forbid the nuptials."

The ministers were again left in a minority, and Shelburne consequently tendered his resignation. It was accepted; but the king struggled long and hard before he submitted to the terms dictated by Fox, whose faults he detested, and whose high spirit and powerful intellect he detested still more. The first place at the board of treasury was repeatedly offered to Pitt; but the offer, though tempting, was steadfastly declined. The young man, whose judgment was as precocious as his disposition, saw that his time was coming, but was not come, and was deaf to royal importunities and requests. His Majesty, bitterly complaining of Pitt's faintheartedness, tried to break the coalition. Every art of seduction was practised on North, but in vain. During several weeks the country remained without a Government. It was not till all devices had failed, and till the aspect of the House of Commons became threatening, that the king gave way. The duke of Portland was declared first lord of the treasury. Thurlow was dismissed. Fox and North ministry. became secretaries of state, with power ostensibly equal. But Fox was the real prime minister.

The year was far advanced before the new arrangements were completed; and nothing very important was done during the remainder of the session. Pitt, now seated on the Opposition bench, brought the question of parliamentary reform a second time under the consideration of the Commons. He proposed to add to the House at once a hundred county members and several members for metropolitan districts, and to enact that every borough of which

Pitt's second motion for parliamentary reform, May 7, 1783.

an election committee should report that the majority of voters appeared to be corrupt should lose the franchise. The motion was rejected by 293 votes to 149.

After the prorogation, Pitt visited the Continent for the first and last time. His travelling companion was one of his most intimate friends, a young man of his own age who had already distinguished himself in parliament by an engaging natural eloquence, set off by the sweetest and most exquisitely modulated of human voices, and whose affectionate heart, caressing manners, and brilliant wit made him the most delightful of companions, William Wilberforce. That was the time of Anglomania in France; and at Paris the son of the great Chatham was absolutely hunted by men of letters and women of fashion, and forced, much against his will, into political disputation. One remarkable saying which dropped from him during this tour has been preserved. A French gentleman expressed some surprise at the immense influence which Fox, a man of pleasure, ruined by the dice-box and the turf, exercised over the English nation. "You have not," said Pitt, "been under the wand of the magician."

State of
parties,
Nov.-
Dec.
1788.

In November 1788 the parliament met again. The Government had irresistible strength in the House of Commons, and seemed to be scarcely less strong in the House of Lords, but was, in truth, surrounded on every side by dangers. The king was impatiently waiting for the moment at which he could emancipate himself from a yoke which galled him so severely that he had more than once seriously thought of retiring to Hanover; and the king was scarcely more eager for a change than the nation. Fox and North had committed a fatal error. They ought to have known that coalitions between parties which have long been hostile can succeed only when the wish for coalition pervades the lower ranks of both. If the leaders unite before there is any disposition to union among the followers, the probability is that there will be a mutiny in both camps, and that the two revolted armies will make a truce with each other in order to be revenged on those by whom they think that they have been betrayed. Thus it was in 1783. At the beginning of that eventful year North had been the recognized head of the old Tory party, which, though for a moment prostrated by the disastrous issue of the American war, was still a great power in the state. To him the clergy, the universities, and that large body of country gentlemen whose rallying cry was "Church and King" had long looked up with respect and confidence. Fox had, on the other hand, been the idol of the Whigs, and of the whole body of Protestant dissenters. The coalition at once alienated the most zealous Tories from North and the most zealous Whigs from Fox. The university of Oxford, which had marked its approbation of North's orthodoxy by electing him chancellor, the city of London, which had been during two and twenty years at war with the court, were equally disgusted. Squires and rectors who had inherited the principles of the cavaliers of the preceding century could not forgive their old leader for combining with disloyal subjects in order to put a force on the sovereign. The members of the Bill of Rights Society and of the reform associations were enraged by learning that their favourite orator now called the great champion of tyranny and corruption his noble friend. Two great multitudes were at once left without any head, and both at once turned their eyes on Pitt. One party saw in him the only man who could rescue the king; the other saw in him the only man who could purify the parliament. He was supported on one side by Archbishop Markham, the preacher of divine right, and by Jenkinson, the captain of the praetorian band of the king's friends; on the other side by Jebb and Priestley, Sawbridge and Cartwright, Jack Wilkes and Horne Tooke. On the

benches of the House of Commons, however, the ranks of the ministerial majority were unbroken; and that any statesman would venture to brave such a majority was thought impossible. No prince of the Hanoverian line had ever, under any provocation, ventured to appeal from the representative body to the constituent body. The ministers, therefore, notwithstanding the sullen looks and muttered words of displeasure with which their suggestions were received in the closet, notwithstanding the roar of obloquy which was rising louder and louder every day from every corner of the island, thought themselves secure.

Such was their confidence in their strength that, as Fox's soon as the parliament had met, they brought forward a singularly bold and original plan for the government of the British territories in India. What was proposed was that the whole authority which till that time had been exercised over those territories by the East India Company should be transferred to seven commissioners, who were to be named by parliament, and were not to be removable at the pleasure of the crown. Earl Fitzwilliam, the most intimate personal friend of Fox, was to be chairman of this board, and the eldest son of North was to be one of the members.

As soon as the outlines of the scheme were known all the hatred which the coalition had excited burst forth with an astounding explosion. The question which ought undoubtedly to have been considered as paramount to every other was whether the proposed change was likely to be beneficial or injurious to the thirty millions of people who were subject to the company. But that question cannot be said to have been even seriously discussed. Burke, who, whether right or wrong in the conclusions to which he came, had at least the merit of looking at the subject in the right point of view, vainly reminded his hearers of that mighty population whose daily rice might depend on a vote of the British parliament. He spoke with even more than his wonted power of thought and language, about the desolation of Rohilcund, about the spoliation of Benares, about the evil policy which had suffered the tanks of the Carnatic to go to ruin; but he could scarcely obtain a hearing. The contending parties, to their shame it must be said, would listen to none but English topics. Out of doors the cry against the ministry was almost universal. Town and country were united. Corporations exclaimed against the violation of the charter of the greatest corporation in the realm. Tories and democrats joined in pronouncing the proposed board an unconstitutional body. It was to consist of Fox's nominees. The effect of his bill was to give, not to the crown, but to him personally, whether in office or in opposition, an enormous power, a patronage sufficient to counterbalance the patronage of the treasury and of the admiralty, and to decide the elections for fifty boroughs. He knew, it was said, that he was hateful alike to king and people; and he had devised a plan which would make him independent of both. Some nicknamed him Cromwell, and some Carlo Khan. Wilberforce, with his usual felicity of expression, and with very unusual bitterness of feeling, described the scheme as the genuine offspring of the coalition, as marked with the features of both its parents, the corruption of one and the violence of the other. In spite of all opposition, however, the bill was supported in every stage by great majorities, was rapidly passed, and was sent up to the Lords. To the general astonishment, when the second reading was moved in the Upper House, the Opposition proposed an adjournment, and carried it by eighty-seven votes to seventy-nine. The cause of this strange turn of fortune was soon known. Pitt's cousin, Earl Temple, had been in the royal closet, and had there

Pitt first
lord
of the
treasury
and chan-
cellor of
the ex-
chequer,
Dec.
1783.

been authorized to let it be known that His Majesty would consider all who voted for the bill as his enemies. The ignominious commission was performed, and instantly a troop of lords of the bedchamber, of bishops who wished to be translated, and of Scotch peers who wished to be re-elected made haste to change sides. On a later day the Lords rejected the bill. Fox and North were immediately directed to send their seals to the palace by their under secretaries; and Pitt was appointed first lord of the treasury and chancellor of the exchequer.

The general opinion was that there would be an immediate dissolution. But Pitt wisely determined to give the public feeling time to gather strength. On this point he differed from his kinsman Temple. The consequence was that Temple, who had been appointed one of the secretaries of state, resigned his office forty-eight hours after he had accepted it, and thus relieved the new Government from a great load of unpopularity; for all men of sense and honour, however strong might be their dislike of the India Bill, disapproved of the manner in which that bill had been thrown out. Temple carried away with him the scandal which the best friends of the new Government could not but lament. The fame of the young prime minister preserved its whiteness. He could declare with perfect truth that, if unconstitutional machinations had been employed, he had been no party to them.

He was, however, surrounded by difficulties and dangers. In the House of Lords, indeed, he had a majority; nor could any orator of the opposition in that assembly be considered as a match for Thurlow, who was now again chancellor, or for Camden, who cordially supported the son of his old friend Chatham. But in the other House there was not a single eminent speaker among the official men who sat round Pitt. His most useful assistant was Dundas, who, though he had not eloquence, had sense, knowledge, readiness, and boldness. On the opposite benches was a powerful majority, led by Fox, who was supported by Burke, North, and Sheridan. The heart of the young minister, stout as it was, almost died within him. He could not once close his eyes on the night which followed Temple's resignation. But, whatever his internal emotions might be, his language and deportment indicated nothing but unconquerable firmness and haughty confidence in his own powers. His contest against the House of Commons lasted from the 17th of December 1783 to the 8th of March 1784. In sixteen divisions the Opposition triumphed. Again and again the king was requested to dismiss his ministers; but he was determined to go to Germany rather than yield. Pitt's resolution never wavered. The cry of the nation in his favour became vehement and almost furious. Addresses assuring him of public support came up daily from every part of the kingdom. The freedom of the city of London was presented to him in a gold box. He went in state to receive this mark of distinction. He was sumptuously feasted in Grocers' Hall; and the shopkeepers of the Strand and Fleet Street illuminated their houses in his honour. These things could not but produce an effect within the walls of parliament. The ranks of the majority began to waver; a few passed over to the enemy; some skulked away; many were for capitulating while it was still possible to capitulate with the honours of war. Negotiations were opened with the view of forming an administration on a wide basis, but they had scarcely been opened when they were closed. The Opposition demanded, as a preliminary article of the treaty, that Pitt should resign the treasury; and with this demand Pitt steadfastly refused to comply. While the contest was raging, the clerkship of the Pells, a sinecure place for life, worth three thousand a year, and tenable with a seat in the House of Commons, became

vacant. The appointment was with the chancellor of the exchequer; nobody doubted that he would appoint himself, and nobody could have blamed him if he had done so; for such sinecure offices had always been defended on the ground that they enabled a few men of eminent abilities and small incomes to live without any profession, and to devote themselves to the service of the state. Pitt, in spite of the remonstrances of his friends, gave the Pells to his father's old adherent, Colonel Barré, a man distinguished by talent and eloquence, but poor and afflicted with blindness. By this arrangement a pension which the Rockingham administration had granted to Barré was saved to the public. Never was there a happier stroke of policy. About treaties, wars, expeditions, tariffs, budgets, there will always be room for dispute. The policy which is applauded by half the nation may be condemned by the other half. But pecuniary disinterestedness everybody comprehends. It is a great thing for a man who has only three hundred a year to be able to show that he considers three thousand a year as mere dirt beneath his feet, when compared with the public interest and the public esteem. Pitt had his reward. No minister was ever more rancorously libelled; but even when he was known to be overwhelmed with debt, when millions were passing through his hands, when the wealthiest magnates of the realm were soliciting him for marquises and garters, his bitterest enemies did not dare to accuse him of touching unlawful gain.

At length the hard-fought fight ended. A final remonstrance, drawn up by Burke with admirable skill, was carried on the 8th of March by a single vote in a full house. Had the experiment been repeated, the supporters of the coalition would probably have been in a minority. But the supplies had been voted; the Mutiny Bill had been passed; and the parliament was dissolved.

The popular constituent bodies all over the country were in general enthusiastic on the side of the new Government. A hundred and sixty of the supporters of the coalition lost their seats. The first lord of the treasury himself came in at the head of the poll for the university of Cambridge. His young friend, Wilberforce, was elected knight of the great shire of York, in opposition to the whole influence of the Fitzwilliams, Cavendishes, Dundases, and Saviles. In the midst of such triumphs Pitt completed his twenty-fifth year. He was now the greatest subject that England had seen during many generations. He domineered absolutely over the cabinet, and was the favourite at once of the sovereign, of the parliament, and of the nation. His father had never been so powerful, nor Walpole, nor Marlborough.

This narrative has now reached a point beyond which a full history of the life of Pitt would be a history of England, or rather of the whole civilized world; and for such a history this is not the proper place. Here a very slight sketch must suffice; and in that sketch prominence will be given to such points as may enable a reader who is already acquainted with the general course of events to form a just notion of the character of the man on whom so much depended.

If we wish to arrive at a correct judgment of Pitt's merits and defects, we must never forget that he belonged to a peculiar class of statesmen, and that he must be tried by a peculiar standard. It is not easy to compare him fairly with such men as Ximenes and Sully, Richelieu and Oxenstiern, John de Witt and Warren Hastings. The means by which those politicians governed great communities were of quite a different kind from those which Pitt was under the necessity of employing. Some talents, which they never had any opportunity of showing that they possessed, were developed in him to an extraordinary degree. In some qualities, on the other hand, to which they owe a large part of their fame, he was decidedly their inferior. They transacted business in their closets, or at boards where a few confidential councillors sat. It was his lot to be born in an age and in a country in which parliamentary government was completely established; his whole training from infancy was such as fitted him to bear a part in parliamentary government; and, from the prime of his manhood to his death, all the powers of his vigorous mind were almost constantly exerted in

Pitt and the work of parliamentary government. He accordingly became the greatest master of the whole art of parliamentary government that has ever existed, a greater than Montague or Walpole, a greater than his father Chatham or his rival Fox, a greater than either of his illustrious successors Canning and Peel.

Parliamentary government, like every other contrivance of man, has its advantages and its disadvantages. On the advantages there is no need to dilate. The history of England during the hundred and seventy years which have elapsed since the House of Commons became the most powerful body in the state, her immense and still growing prosperity, her freedom, her tranquillity, her greatness in arts, in sciences, and in arms, her maritime ascendancy, the marvels of her public credit, her American, her African, her Australian, her Asiatic empires, sufficiently prove the excellence of her institutions. But those institutions, though excellent, are assuredly not perfect. Parliamentary government is government by speaking. In such a government, the power of speaking is the most highly prized of all the qualities which a politician can possess; and that power may exist, in the highest degree, without judgment, without fortitude, without skill in reading the characters of men or the signs of the times, without any knowledge of the principles of legislation or of political economy, and without any skill in diplomacy or in the administration of war. Nay, it may well happen that those very intellectual qualities which give a peculiar charm to the speeches of a public man may be incompatible with the qualities which would fit him to meet a pressing emergency with promptitude and firmness. It was thus with Charles Townshend. It was thus with Windham. It was a privilege to listen to those accomplished and ingenious orators. But in a perilous crisis they would have been found far inferior in all the qualities of rulers to such a man as Oliver Cromwell, who talked nonsense, or as William the Silent, who did not talk at all. When parliamentary government is established, a Charles Townshend or a Windham will almost always exercise much greater influence than such men as the great Protector of England, or as the founder of the Batavian commonwealth. In such a government, parliamentary talent, though quite distinct from the talents of a good executive or judicial officer, will be a chief qualification for executive and judicial office. From the Book of Dignities a curious list might be made out of chancellors ignorant of the principles of equity, and first lords of the admiralty ignorant of the principles of navigation, of colonial ministers who could not repeat the names of the colonies, of lords of the treasury who did not know the difference between funded and unfunded debt, and of secretaries of the India board who did not know whether the Mahrattas were Mohammedans or Hindus. On these grounds, some persons, incapable of seeing more than one side of a question, have pronounced parliamentary government a positive evil, and have maintained that the administration would be greatly improved if the power, now exercised by a large assembly, were transferred to a single person. Men of sense will probably think the remedy very much worse than the disease, and will be of opinion that there would be small gain in exchanging Charles Townshend and Windham for the Prince of the Peace, or the poor slave and dog Steenie.

Pitt was emphatically the man of parliamentary government, the type of his class, the minion, the child, the spoiled child, of the House of Commons. For the House of Commons he had a hereditary, an infantine love. Through his whole boyhood the House of Commons was never out of his thoughts, or out of the thoughts of his instructors. Reciting at his father's knee, reading Thucydides and Cicero into English, analysing the great Attic speeches on the Embassy and on the Crown, he was constantly in training for the conflicts of the House of Commons. He was a distinguished member of the House of Commons at twenty-one. The ability which he had displayed in the House of Commons made him the most powerful subject in Europe before he was twenty-five. It would have been happy for himself and for his country if his elevation had been deferred. Eight or ten years, during which he would have had leisure and opportunity for reading and reflexion, for foreign travel, for social intercourse and free exchange of thought on equal terms with a great variety of companions, would have supplied what, without any fault on his part, was wanting to his powerful intellect. He had all the knowledge that he could be expected to have—that is to say, all the knowledge that a man can acquire while he is a student at Cambridge, and all the knowledge that a man can acquire when he is first lord of the treasury and chancellor of the exchequer. But the stock of general information which he brought from college, extraordinary for a boy, was far inferior to what Fox possessed, and beggarly when compared with the massy, the splendid, the various treasures laid up in the large mind of Burke. After Pitt became minister, he had no leisure to learn more than was necessary for the purposes of the day which was passing over him. What was necessary for those purposes such a man could learn with little difficulty. He was surrounded by experienced and able public servants. He could at any moment command their best assistance. From the stores which they produced his vigorous mind rapidly collected the

materials for a good parliamentary case; and that was enough. Legislation and administration were with him secondary matters. To the work of framing statutes, of negotiating treaties, of organizing fleets and armies, of sending forth expeditions, he gave only the leavings of his time and the dregs of his fine intellect. The strength and sap of his mind were all drawn in a different direction. It was when the House of Commons was to be convinced and persuaded that he put forth all his powers.

Of those powers we must form our estimate chiefly from tradition; His for, of all the eminent speakers of the last age, Pitt has suffered oratory most from the reporters. Even while he was still living, critics remarked that his eloquence could not be preserved, that he must be heard to be appreciated. They more than once applied to him the sentence in which Tacitus describes the fate of a senator whose rhetoric was admired in the Augustan age: "*Haterii canorillud et profuens cum ipso simul extinctum est.*" There is, however, abundant evidence that nature had bestowed on Pitt the talents of a great orator; and those talents had been developed in a very peculiar manner, first by his education, and secondly by the high official position to which he rose early, and in which he passed the greater part of his public life.

At his first appearance in parliament he showed himself superior to all his contemporaries in command of language. He could pour forth a long succession of round and stately periods, without premeditation, without ever pausing for a word, without ever repeating a word, in a voice of silver clearness, and with a pronunciation so articulate that not a letter was slurred over. He had less amplitude of mind and less richness of imagination than Burke, less ingenuity than Windham, less wit than Sheridan, less perfect mastery of dialectical fence and less of that highest sort of eloquence which consists of reason and passion fused together than Fox. Yet the almost unanimous judgment of those who were in the habit of listening to that remarkable race of men placed Pitt, as a speaker, above Burke, above Windham, above Sheridan, and not below Fox. His declamation was copious, polished, and splendid. In power of sarcasm he was probably not surpassed by any speaker, ancient or modern; and of this formidable weapon he made merciless use. In two parts of the oratorical art which are of the highest value to a minister of state he was singularly expert. No man knew better how to be luminous or how to be obscure. When he wished to be understood, he never failed to make himself understood. He could with ease present to his audience, not perhaps an exact or profound, but a clear, popular, and plausible view of the most extensive and complicated subject. Nothing was out of place; nothing was forgotten; minute details, dates, sums of money, were all faithfully preserved in his memory. Even intricate questions of finance, when explained by him, seemed clear to the plainest man among his hearers. On the other hand, when he did not wish to be explicit,—and no man who is at the head of affairs always wishes to be explicit,—he had a marvellous power of saying nothing in language which left on his audience the impression that he had said a great deal. He was at once the only man who could open a budget without notes, and the only man who, as Windham said, could speak that most elaborately evasive and unmeaning of human compositions, a king's speech, without premeditation.

The effect of oratory will always to a great extent depend on the Personal character of the orator. There perhaps never were two speakers whose eloquence had more of what may be called the race, more of the flavour imparted by moral qualities, than Fox and Pitt. The speeches of Fox owe a great part of their charm to that warmth and softness of heart, that sympathy with human suffering, that admiration for everything great and beautiful, and that hatred of cruelty and injustice, which interest and delight us even in the most defective reports. No person, on the other hand, could hear Pitt without perceiving him to be a man of high, intrepid, and commanding spirit, proudly conscious of his own rectitude and of his own intellectual superiority, incapable of the low vices of fear and envy, but too prone to feel and to show disdain. Pride, indeed, pervaded the whole man, was written in the harsh, rigid lines of his face, was marked by the way in which he walked, in which he sat, in which he stood, and, above all, in which he bowed. Such pride, of course, inflicted many wounds. It may confidently be affirmed that there cannot be found, in all the ten thousand invectives written against Fox, a word indicating that his demeanour had ever made a single personal enemy. On the other hand, several men of note who had been partial to Pitt, and who to the last continued to approve his public conduct and to support his administration—Cumberland, for example, Boswell, and Matthias—were so much irritated by the contempt with which he treated them, that they complained in print of their wrongs. But his pride, though it made him bitterly disliked by individuals, inspired the great body of his followers in parliament and throughout the country with respect and confidence. They took him at his own valuation. They saw that his self-esteem was not that of an upstart who was drunk with good luck and with applause, and who, if fortune turned, would sink from arrogance into abject humility. It was that of the magnanimous man so finely described by Aristotle in

the *Ethics*, of the man who thinks himself worthy of great things, being in truth worthy. It sprang from a consciousness of great powers and great virtues, and was never so conspicuously displayed as in the midst of difficulties and dangers which would have unnerved and bowed down any ordinary mind. It was closely connected, too, with an ambition which had no mixture of low cupidity. There was something noble in the cynical disdain with which the mighty minister scattered riches and titles to right and left among those who valued them, while he spurned them out of his way. Poor himself, he was surrounded by friends on whom he had bestowed three thousand, six thousand, ten thousand a year. Plain Mister himself, he had made more lords than any three ministers that had preceded him. The garter, for which the first dukes in the kingdom were contending, was repeatedly offered to him, and offered in vain.

Private life.

The correctness of his private life added much to the dignity of his public character. In the relations of son, brother, uncle, master, friend, his conduct was exemplary. In the small circle of his intimate associates he was amiable, affectionate, even playful. They loved him sincerely; they regretted him long; and they would hardly admit that he who was so kind and gentle with them could be stern and haughty with others. He indulged, indeed, somewhat too freely in wine, which he had early been directed to take as a medicine, and which use had made a necessary of life to him. But it was very seldom that any indication of undue excess could be detected in his tones or gestures; and, in truth, two bottles of port were little more to him than two dishes of tea. He had, when he was first introduced into the clubs of St James's Street, shown a strong taste for play; but he had the prudence and the resolution to stop before this taste had acquired the strength of habit. From the passion which generally exercises the most tyrannical dominion over the young he possessed an immunity, which is probably to be ascribed partly to his temperament and partly to his situation. His constitution was feeble; he was very shy; and he was very busy. The strictness of his morals furnished such buffoons as Peter Pindar and Captain Morris with an inexhaustible theme for merriment of no very delicate kind. But the great body of the middle class of Englishmen could not see the joke. They warmly praised the young statesman for commanding his passions, and for covering his frailties, if he had frailties, with decorous obscurity, and would have been very far indeed from thinking better of him if he had vindicated himself from the taunts of his enemies by taking under his protection a Nancy Parsons or a Marianne Clark.

Patronage of letters and art.

No part of the immense popularity which Pitt long enjoyed is to be attributed to the eulogies of wits and poets. It might have been naturally expected that a man of genius, of learning, of taste, an orator whose diction was often compared to that of Tully, the representative, too, of a great university, would have taken a peculiar pleasure in befriending eminent writers to whatever political party they might have belonged. The love of literature had induced Augustus to heap benefits on Pompeians, Somers to be the protector of nonjurors, Harley to make the fortunes of Whigs. But it could not move Pitt to show any favour even to Pittites. He was doubtless right in thinking that, in general, poetry, history, and philosophy ought to be suffered, like calico and cutlery, to find their proper price in the market, and that to teach men of letters to look habitually to the state for their recompense is bad for the state and bad for letters. Assuredly nothing can be more absurd or mischievous than to waste the public money in bounties for the purpose of inducing people who ought to be weighing out grocery or measuring out drapery to write bad or middling books. But, though the sound rule is that authors should be left to be remunerated by their readers, there will, in every generation, be a few exceptions to this rule. To distinguish these special cases from the mass is an employment well worthy of the faculties of a great and accomplished ruler; and Pitt would assuredly have had little difficulty in finding such cases. While he was in power, the greatest philologist of the age, his own contemporary at Cambridge, was reduced to earn a livelihood by the lowest literary drudgery, and to spend in writing squibs for the *Morning Chronicle* years to which we might have owed an all but perfect text of the whole tragic and comic drama of Athens. The greatest historian of the age, forced by poverty to leave his country, completed his immortal work on the shores of Lake Leman. The political heterodoxy of Porson and the religious heterodoxy of Gibbon may perhaps be pleaded in defence of the minister by whom those eminent men were neglected. But there were other cases in which no such excuse could be set up. Scarcely had Pitt obtained possession of unbounded power when an aged writer of the highest eminence, who had made very little by his writings, and who was sinking into the grave under a load of infirmities and sorrows, wanted five or six hundred pounds to enable him, during the winter or two which might still remain to him, to draw his breath more easily in the soft climate of Italy. Not a farthing was to be obtained; and before Christmas the author of the *English Dictionary* and of the *Lives of the Poets* had gasped his last in the

river fog and coal smoke of Fleet Street. A few months after the death of Johnson appeared the *Task*, incomparably the best poem that any Englishman then living had produced—a poem, too, which could hardly fail to excite in a well-constituted mind a feeling of esteem and compassion for the poet, a man of genius and virtue, whose means were scanty, and whom the most cruel of all the calamities incident to humanity had made incapable of supporting himself by vigorous and sustained exertion. Nowhere had Chatham been praised with more enthusiasm, or in verse more worthy of the subject, than in the *Task*. The son of Chatham, however, contented himself with reading and admiring the book, and left the author to starve. The pension which long after enabled poor Cowper to close his melancholy life unmolested by duns and bailiffs was obtained for him by the strenuous kindness of Lord Spencer. What a contrast between the way in which Pitt acted towards Johnson and the way in which Lord Grey acted towards his political enemy Scott, when Scott, worn out by misfortune and disease, was advised to try the effect of the Italian air! What a contrast between the way in which Pitt acted towards Cowper and the way in which Burke, a poor man and out of place, acted towards Crabbe! Even Dundas, who made no pretensions to literary taste, and was content to be considered as a hard-headed and somewhat coarse man of business, was, when compared with his eloquent and classically educated friend, a Mæcenas or a Leo. Dundas made Burns an exciseman, with seventy pounds a year; and this was more than Pitt, during his long tenure of power, did for the encouragement of letters. Even those who may think that it is, in general, no part of the duty of a Government to reward literary merit, will hardly deny that a Government which has much lucrative church preferment in its gift is bound, in distributing that preferment, not to overlook divines whose writings have rendered great service to the cause of religion. But it seems never to have occurred to Pitt that he lay under any such obligation. All the theological works of all the numerous bishops whom he made and translated are not, when put together, worth fifty pages of the *Horæ Paulinæ*, of the *Natural Theology*, or of the *View of the Evidences of Christianity*. But on Paley the all-powerful minister never bestowed the smallest benefice. Artists Pitt treated as contemptuously as writers. For painting he did simply nothing. Sculptors who had been selected to execute monuments voted by parliament had to haunt the ante-chambers of the treasury during many years before they could obtain a farthing from him. One of them, after vainly soliciting the minister for payment during fourteen years, had the courage to present a memorial to the king, and thus obtained tardy and ungracious justice. Architects it was absolutely necessary to employ; and the worst that could be found seem to have been employed. Not a single fine public building of any kind or in any style was erected during his long administration. It may be confidently affirmed that no ruler whose abilities and attainments would bear any comparison with his has ever shown such cold disdain for what is excellent in arts and letters.

His first administration lasted seventeen years. That long First ad-period is divided by a strongly marked line into two almost exactly ministrual parts. The first part ended and the second began in the tion, autumn of 1792. Throughout both parts Pitt displayed in the 1784–highest degree the talents of a parliamentary leader. During the 1801. first part he was a fortunate and in many respects a skillful administrator. With the difficulties which he had to encounter during the second part he was altogether incapable of contending; but his eloquence and his perfect mastery of the tactics of the House of Commons concealed his incapacity from the multitude.

The eight years which followed the general election of 1784 were First as tranquil and prosperous as any eight years in the whole history period, of England. Neighbouring nations which had lately been in arms 1784–against her, and which had flattered themselves that, in losing her 1792. American colonies, she had lost a chief source of her wealth and of her power, saw, with wonder and vexation, that she was more wealthy and more powerful than ever. Her trade increased. Her manufactures flourished. Her exchequer was full to overflowing. Very idle apprehensions were generally entertained that the public debt, though much less than a third of the debt which we now bear with ease, would be found too heavy for the strength of the nation. Those apprehensions might not perhaps have been easily quieted by reason. But Pitt quieted them by a juggle. He succeeded in persuading first himself and then the whole nation, his opponents included, that a new sinking fund, which, so far as it differed from former sinking funds, differed for the worse, would, by virtue of some mysterious power of propagation belonging to money, put into the pocket of the public creditor great sums not taken out of the pocket of the tax-payer. The country, terrified by a danger which was no danger, hailed with delight and boundless confidence a remedy which was no remedy. The minister was almost universally extolled as the greatest of financiers. Meanwhile both the branches of the house of Bourbon found that England was as formidable an antagonist as she had ever been. France had formed a plan for reducing Holland to vassalage. But England interposed, and France receded. Spain interrupted by

violence the trade of our merchants with the regions near the Oregon. But England armed, and Spain receded. Within the island there was profound tranquillity. The king was, for the first time, popular. During the twenty-three years which had followed his accession he had not been loved by his subjects. His domestic virtues were acknowledged. But it was generally thought that the good qualities by which he was distinguished in private life were wanting to his political character. As a sovereign he was resentful, unforgiving, stubborn, cunning. Under his rule the country had sustained cruel disgraces and disasters; and every one of those disgraces and disasters was imputed to his strong antipathies, and to his perverse obstinacy in the wrong. One statesman after another complained that he had been induced by royal caresses, entreaties, and promises to undertake the direction of affairs at a difficult conjuncture, and that as soon as he had, not without sullyng his fame and alienating his best friends, served the turn for which he was wanted, his ungrateful master began to intrigue against him and to canvass against him. Grenville, Rockingham, Chatham—men of widely different characters, but all three upright and high-spirited—agreed in thinking that the prince under whom they had successively held the highest place in the Government was one of the most insincere of mankind. His confidence was reposed, they said, not in those known and responsible counsellors to whom he had delivered the seals of office, but in secret advisers who stole up the back stairs into his closet. In parliament his ministers, while defending themselves against the attacks of the opposition in front, were perpetually, at his instigation, assailed on the flank or in the rear by a vile band of mercenaries who called themselves his friends. These men constantly, while in possession of lucrative places in his service, spoke and voted against bills which he had authorized the first lord of the treasury or the secretary of state to bring in. But from the day on which Pitt was placed at the head of affairs there was an end of secret influence. His haughty and aspiring spirit was not to be satisfied with the mere show of power. Any attempt to undermine him at court, any mutinous movement among his followers in the House of Commons, was certain to be at once put down. He had only to tender his resignation and he could dictate his own terms. For he, and he alone, stood between the king and the coalition. He was therefore little less than mayor of the palace. The nation loudly applauded the king for having the wisdom to repose entire confidence in so excellent a minister. His Majesty's private virtues now began to produce their full effect. He was generally regarded as the model of a respectable country gentleman, honest, good-natured, sober, religious. He rose early, he dined temperately, he was strictly faithful to his wife, he never missed church, and at church he never missed a response. His people heartily prayed that he might long reign over them; and they prayed the more heartily because his virtues were set off to the best advantage by the vices and follies of the prince of Wales, who lived in close intimacy with the chiefs of the Opposition.

The regency, 1788. How strong this feeling was in the public mind appeared signally on one great occasion. In the autumn of 1788 the king became insane. The Opposition, eager for office, committed the great indiscretion of asserting that the heir apparent had, by the fundamental laws of England, a right to be regent with the full powers of royalty. Pitt, on the other hand, maintained it to be the constitutional doctrine that when a sovereign is, by reason of infancy, disease, or absence, incapable of exercising the regal functions, it belongs to the estates of the realm to determine who shall be the vicegerent, and with what portion of the executive authority such vicegerent shall be entrusted. A long and violent contest followed, in which Pitt was supported by the great body of the people with as much enthusiasm as during the first months of his administration. Tories with one voice applauded him for defending the sick-bed of a virtuous and unhappy sovereign against a disloyal faction and an undutiful son. Not a few Whigs applauded him for asserting the authority of parliaments, and the principles of the Revolution, in opposition to a doctrine which seemed to have too much affinity with the servile theory of indefeasible hereditary right. The middle class, always zealous on the side of decency and the domestic virtues, looked forward with dismay to a reign resembling that of Charles II. The palace, which had now been, during thirty years, the pattern of an English home, would be a public nuisance, a school of profligacy. To the good king's repast of mutton and lemonade, despatched at three o'clock, would succeed midnight banquets, from which the guests would be carried home speechless. To the backgammon board at which the good king played for a little silver with his equerries would succeed faro tables from which young patricians who had sat down rich would rise up beggars. The drawing-room, from which the frown of the queen had repelled a whole generation of frail beauties, would now be again what it had been in the days of Barbara Palmer and Louisa de Querouaille. Nay, severely as the public reprobated the prince's many illicit attachments, his one virtuous attachment was reprobated more severely still. Even in grave and pious circles his Protestant mistresses gave less scandal than his Popish wife. That he must

be regent nobody ventured to deny. But he and his friends were so unpopular that Pitt could, with general approbation, propose to limit the powers of the regent by restrictions to which it would have been impossible to subject a prince beloved and trusted by the country. Some interested men, fully expecting a change of administration, went over to the Opposition. But the majority, purified by these desertions, closed its ranks, and presented a more firm array than ever to the enemy. In every division Pitt was victorious. When at length, after a stormy interregnum of three months, it was announced, on the very eve of the inauguration of the regent, that the king was himself again, the nation was wild with delight. On the evening of the day on which His Majesty resumed his functions a spontaneous illumination, the most general that had ever been seen in England, brightened the whole vast space from Highgate to Tooting, and from Hammersmith to Greenwich. On the day on which he returned thanks in the cathedral of his capital all the horses and carriages within a hundred miles of London were too few for the multitudes which flocked to see him pass through the streets. A second illumination followed, which was even superior to the first in magnificence. Pitt with difficulty escaped from the tumultuous kindness of an innumerable multitude which insisted on drawing his coach from St Paul's Churchyard to Downing Street. This was the moment at which his fame and fortune may be said to have reached the zenith. His influence in the closet was as great as that of Carr or Villiers had been. His dominion over the parliament was more absolute than that of Walpole or Pelham had been. He was at the same time as high in the favour of the populace as ever Wilkes or Sackville had been. Nothing did more to raise his character than his noble poverty. It was well known that, if he had been dismissed from office after more than five years of boundless power, he would hardly have carried out with him a sum sufficient to furnish the set of chambers in which, as he cheerfully declared, he meant to resume the practice of the law. His admirers, however, were by no means disposed to suffer him to depend on daily toil for his daily bread. The voluntary contributions which were awaiting his acceptance in the city of London alone would have sufficed to make him a rich man. But it may be doubted whether his haughty spirit would have stooped to accept a provision so honourably earned and so honourably bestowed.

To such a height of power and glory had this extraordinary man risen at twenty-nine years of age. And now the tide was on the turn. Only ten days after the triumphant procession to St Paul's, the states-general of France, after an interval of a hundred and seventy-four years, met at Versailles.

The nature of the great Revolution which followed was long very French imperfectly understood in this country. Burke saw much further Revolution than any of his contemporaries; but whatever his sagacity described was refracted and discoloured by his passions and his imagination. More than three years elapsed before the principles of the English administration underwent any material change. Nothing could as yet be milder or more strictly constitutional than the minister's domestic policy. Not a single act indicating an arbitrary temper or a jealousy of the people could be imputed to him. He had never applied to parliament for any extraordinary powers. He had never used with harshness the ordinary powers entrusted by the constitution to the executive Government. Not a single state prosecution which would even now be called oppressive had been instituted by him. Indeed, the only oppressive state prosecution instituted during the first eight years of his administration was that of Stockdale, which is to be attributed, not to the Government, but to the chiefs of the Opposition. In office, Pitt had redeemed the pledges which he had, at his entrance into public life, given to the supporters of parliamentary reform. He had, in 1785, brought forward a judicious plan for the improvement of the representative system, and had prevailed on the king, not only to refrain from talking against that plan, but to recommend it to the Houses in a speech from the throne.¹ This attempt failed; but there can be little doubt that, if the French Revolution had not produced a violent reaction of public feeling, Pitt would have performed, with little difficulty and no danger, that great work which, at a later period, Lord Grey could accomplish only by means which for a time loosened the very foundations of the commonwealth. When the atrocities of the slave trade were first brought under the consideration of parliament, no abolitionist was more zealous than Pitt. When sickness prevented Wilberforce from appearing in public, his place was most efficiently supplied by his friend the minister. A humane bill, which mitigated the horrors of the middle passage, was, in 1788, carried by the eloquence and determined spirit of Pitt, in spite of the opposition of some of his own colleagues; and it ought always to be remembered to his honour that, in order to carry that bill, he kept the Houses sitting, in spite of many murmurs, long after the business of the Government had been done

¹ The speech with which the king opened the session of 1785 concluded with an assurance that His Majesty would heartily concur in every measure which could tend to secure the true principles of the constitution. These words were at the time understood to refer to Pitt's Reform Bill.

and the Appropriation Act passed. In 1791 he cordially concurred with Fox in maintaining the sound constitutional doctrine that an impeachment is not terminated by a dissolution. In the course of the same year the two great rivals contended side by side in a far more important cause. They are fairly entitled to divide the high honour of having added to our statute-book the inestimable law which places the liberty of the press under the protection of juries. On one occasion, and one alone, Pitt, during the first half of his long administration, acted in a manner unworthy of an enlightened Whig. In the debate on the Test Act, he stooped to gratify the master whom he served, the university which he represented, and the great body of clergymen and country gentlemen on whose support he rested, by talking, with little heartiness indeed, and with no asperity, the language of a Tory. With this single exception, his conduct from the end of 1783 to the middle of 1792 was that of an honest friend of civil and religious liberty.

Nor did anything, during that period, indicate that he loved war, or harboured any malevolent feeling against any neighbouring nation. Those French writers who have represented him as a Hannibal sworn in childhood by his father to bear eternal hatred to France, as having, by mysterious intrigues and lavish bribes, instigated the leading Jacobins to commit those excesses which dishonoured the Revolution, as having been the real author of the first coalition, know nothing of his character or of his history. So far was he from being a deadly enemy to France that his laudable attempts to bring about a closer connexion with that country by means of a wise and liberal treaty of commerce brought on him the severe censure of the Opposition. He was told in the House of Commons that he was a degenerate son, and that his partiality for the hereditary foes of our island was enough to make his great father's bones stir under the pavement of the Abbey.

Its influence in English politics.

And this man, whose name, if he had been so fortunate as to die in 1792, would now have been associated with peace, with freedom, with philanthropy, with temperate reform, with mild and constitutional administration, lived to associate his name with arbitrary government, with harsh laws harshly executed, with alien bills, with gagging bills, with suspensions of the Habeas Corpus Act, with cruel punishments inflicted on some political agitators, with unjustifiable prosecutions instituted against others, and with the most costly and most sanguinary wars of modern times. He lived to be held up to obloquy as the stern oppressor of England, and the indefatigable disturber of Europe. Poets, contrasting his earlier with his later years, likened him sometimes to the apostle who kissed in order to betray, and sometimes to the evil angels who kept not their first estate. A satirist of great genius introduced the fiends of famine, slaughter, and fire, proclaiming that they had received their commission from one whose name was formed of four letters, and promising to give their employer ample proofs of gratitude. Famine would gnaw the multitude till they should rise up against him in madness. The demon of slaughter would impel them to tear him from limb to limb. But fire boasted that she alone could reward him as he deserved, and that she would cling round him to all eternity. By the French press and the French tribune every crime that disgraced and every calamity that afflicted France was ascribed to the monster Pitt and his guineas. While the Jacobins were dominant it was he who had corrupted the Gironde, who had raised Lyons and Bordeaux against the Convention, who had suborned Paris to assassinate Lepelletier, and Cecilia Regnault to assassinate Robespierre. When the Thermidorian reaction came, all the atrocities of the Reign of Terror were imputed to him. Collet D'Herbois and Fouquier Tinville had been his pensioners. It was he who had hired the murderers of September, who had dictated the pamphlets of Marat and the carnagnoles of Barère, who had paid Lebon to deluge Arras with blood and Carrier to choke the Loire with corpses.

The truth is that he liked neither war nor arbitrary government. He was a lover of peace and freedom, driven, by a stress against which it was hardly possible for any will or any intellect to struggle, out of the course to which his inclinations pointed, and for which his abilities and acquirements fitted him, and forced into a policy repugnant to his feelings and unsuited to his talents.

The charge of apostasy is grossly unjust. A man ought no more to be called an apostate because his opinions alter with the opinions of the great body of his contemporaries than he ought to be called an Oriental traveller because he is always going round from west to east with the globe and everything that is upon it. Between the spring of 1789 and the close of 1792 the public mind of England underwent a great change. If the change of Pitt's sentiments attracted peculiar notice, it was not because he changed more than his neighbours, for in fact he changed less than most of them, but because his position was far more conspicuous than theirs, because he was, till Bonaparte appeared, the individual who filled the greatest space in the eyes of the inhabitants of the civilized world. During a short time the nation, and Pitt as one of the nation, looked with interest and approbation on the French Revolution. But soon vast confiscations, the violent sweeping away of ancient institutions, the domination of clubs, the barbarities of mobs

maddened by famine and hatred, produced a reaction here. The court, the nobility, the gentry, the clergy, the manufacturers, the merchants, in short nineteen-twentieths of those who had good roofs over their heads and good coats on their backs, became eager intolerant Antijacobins. This feeling was at least as strong among the minister's adversaries as among his supporters. Fox in vain attempted to restrain his followers. All his genius, all his vast personal influence, could not prevent them from rising up against him in general mutiny. Burke set the example of revolt; and Burke was in no long time joined by Portland, Spencer, Fitzwilliam, Loughborough, Carlisle, Malmesbury, Windham, Elliot. In the House of Commons the followers of the great Whig statesman and orator diminished from about a hundred and sixty to fifty. In the House of Lords he had but ten or twelve adherents left. There can be no doubt that there would have been a similar mutiny on the ministerial benches, if Pitt had obstinately resisted the general wish. Pressed at once by his master and by his colleagues, by old friends and by old opponents, he abandoned, slowly and reluctantly, the policy which was dear to his heart. He laboured hard to avert the European war. When the European war broke out, he still flattered himself that it would not be necessary for this country to take either side. In the spring of 1792 he congratulated the parliament on the prospect of long and profound peace, and proved his sincerity by proposing large remissions of taxation. Down to the end of that year he continued to cherish the hope that England might be able to preserve neutrality. But the passions which raged on both sides of the Channel were not to be restrained. The republicans who ruled France were inflamed by a fanaticism resembling that of the Mussulmans, who, with the Koran in one hand and the sword in the other, went forth conquering and converting, eastward to the Bay of Bengal, and westward to the Pillars of Hercules. The higher and middle classes of England were animated by zeal not less fiery than that of the crusaders who raised the cry of *Deus vult* at Clermont. The impulse which drove the two nations to a collision was not to be arrested by the abilities or by the authority of any single man. As Pitt was in front of his fellows, and towered high above them, he seemed to lead them. But in fact he was violently pushed on by them, and, had he held back but a little more than he did, would have been thrust out of their way or trampled under their feet.

He yielded to the current; and from that day his misfortunes began. The truth is that there were only two consistent courses period before him. Since he did not choose to oppose himself, side by side with Fox, to the public feeling, he should have taken the administrative advice of Burke, and should have availed himself of that feeling to traction, the full extent. If it was impossible to preserve peace, he should 1792—have adopted the only policy which could lead to victory. He 1801. should have proclaimed a holy war for religion, morality, property, order, public law, and should have thus opposed to the Jacobins an energy equal to their own. Unhappily he tried to find a middle path; and he found one which united all that was worst in both extremes. He went to war; but he would not understand the War peculiar character of that war. He was obstinately blind to the plain fact that he was contending against a state which was also a sect, and that the new quarrel between England and France was of quite a different kind from the old quarrels about colonies in America and fortresses in the Netherlands. He had to combat frantic enthusiasm, boundless ambition, restless activity, the wildest and most audacious spirit of innovation; and he acted as if he had had to deal with the harlots and fops of the old court of Versailles, with Madame de Pompadour and the Abbé de Bernis. It was pitiable to hear him, year after year, proving to an admiring audience that the wicked republic was exhausted, that she could not hold out, that her credit was gone, that her assignats were not worth more than the paper of which they were made,—as if credit was necessary to a government of which the principle was rapine, as if Alboin could not turn Italy into a desert till he had negotiated a loan at five per cent., as if the exchequer bills of Attila had been at par. It was impossible that a man who so completely mistook the nature of a contest could carry on that contest successfully. Great as Pitt's abilities were, his military administration was that of a driveller. He was at the head of a nation Military engaged in a struggle for life and death, of a nation eminently dis-administrated by all the physical and all the moral qualities which tration. make excellent soldiers. The resources at his command were unlimited. The parliament was even more ready to grant him men and money than he was to ask for them. In such an emergency, and with such means, such a statesman as Richelieu, as Louvois, as Chatham, as Wellesley, would have created in a few months one of the finest armies in the world, and would soon have discovered and brought forward generals worthy to command such an army. Germany might have been saved by another Blenheim; Flanders recovered by another Ramillies; another Poitiers might have delivered the Royalist and Catholic provinces of France from a yoke which they abhorred, and might have spread terror even to the barriers of Paris. But the fact is that, after eight years of war, after a vast destruction of life, after an expenditure of wealth

far exceeding the expenditure of the American War, of the Seven Years' War, of the War of the Austrian Succession, and of the War of the Spanish Succession united, the English army under Pitt was the laughing-stock of all Europe. It could not boast of one single brilliant exploit. It had never shown itself on the Continent but to be beaten, chased, forced to re-embark, or forced to capitulate. To take some sugar island in the West Indies, to scatter some mob of half-naked Irish peasants—such were the most splendid victories won by the British troops under Pitt's auspices.

Naval
adminis-
tration.

The English navy no mismanagement could ruin. But during a long period whatever mismanagement could do was done. The earl of Chatham, without a single qualification for high public trust, was made, by fraternal partiality, first lord of the admiralty, and was kept in that great post during two years of a war in which the very existence of the state depended on the efficiency of the fleet. He continued to doze away and trifle away the time which ought to have been devoted to the public service, till the whole mercantile body, though generally disposed to support the Government, complained bitterly that our flag gave no protection to our trade. Fortunately he was succeeded by George, Earl Spencer, one of those chiefs of the Whig party who, in the great schism caused by the French Revolution, had followed Burke. Lord Spencer, though inferior to many of his colleagues as an orator, was decidedly the best administrator among them. To him it was owing that a long and gloomy succession of days of fasting, and most emphatically of humiliation, was interrupted, twice in the short space of eleven months, by days of thanksgiving for great victories.

It may seem paradoxical to say that the incapacity which Pitt showed in all that related to the conduct of the war is, in some sense, the most decisive proof that he was a man of very extraordinary abilities. Yet this is the simple truth. For assuredly one-tenth part of his errors and disasters would have been fatal to the power and influence of any minister who had not possessed, in the highest degree, the talents of a parliamentary leader. While his schemes were confounded, while his predictions were falsified, while the coalitions which he had laboured to form were falling to pieces, while the expeditions which he had sent forth at enormous cost were ending in rout and disgrace, while the enemy against whom he was feebly contending was subjugating Flanders and Brabant, the electorate of Mainz and the electorate of Treves, Holland, Piedmont, Liguria, Lombardy, his authority over the House of Commons was constantly becoming more and more absolute. There was his empire. There were his victories—his Lodi and his Arcola, his Rivoli and his Marengo. If some great misfortune, a pitched battle lost by the allies, the annexation of a new department to the French republic, a sanguinary insurrection in Ireland, a mutiny in the fleet, a panic in the city, a run on the bank, had spread dismay through the ranks of his majority, that dismay lasted only till he rose from the treasury bench, drew up his haughty head, stretched his arm with commanding gesture, and poured forth, in deep and sonorous tones, the lofty language of inextinguishable hope and inflexible resolution. Thus, through a long and calamitous period, every disaster that happened without the walls of parliament was regularly followed by a triumph within them. At length he had no longer an Opposition to encounter. Of the great party which had contended against him during the first eight years of his administration more than one-half now marched under his standard, with his old competitor the duke of Portland at their head; and the rest had, after many vain struggles, quitted the field in despair. Fox had retired to the shades of St Anne's Hill, and had there found, in the society of friends whom no vicissitude could estrange from him, of a woman whom he tenderly loved, and of the illustrious dead of Athens, of Rome, and of Florence, ample compensation for all the misfortunes of his public life. Session followed session with scarcely a single division. In the eventful year 1799 the largest minority that could be mustered against the Government was twenty-five.

Domestic
policy.

In Pitt's domestic policy there was at this time assuredly no want of vigour. While he offered to French Jacobinism a resistance so feeble that it only encouraged the evil which he wished to suppress, he put down English Jacobinism with a strong hand. The Habeas Corpus Act was repeatedly suspended. Public meetings were placed under severe restraints. The Government obtained from parliament power to send out of the country aliens who were suspected of evil designs; and that power was not suffered to be idle. Writers who propounded doctrines adverse to monarchy and aristocracy were proscribed and punished without mercy. It was hardly safe for a republican to avow his political creed over his beefsteak and his bottle of port at a chop-house. The old laws of Scotland against sedition, laws which were considered by Englishmen as barbarous, and which a succession of Governments had suffered to rust, were now furnished up and sharpened anew. Men of cultivated minds and polished manners were, for offences which at Westminster would have been treated as mere misdemeanours, sent to herd with felons at Botany Bay. Some reformers, whose opinions were extravagant, and whose language was intemperate, but who had never dreamed of subverting the

government by physical force, were indicted for high treason, and were saved from the gallows only by the righteous verdicts of juries. This severity was at the time loudly applauded by alarmists whom fear had made cruel, but will be seen in a very different light by posterity. The truth is that the Englishmen who wished for a revolution were, even in number, not formidable, and in everything but number a faction utterly contemptible, without arms, or funds, or plans, or organization, or leader. There can be no doubt that Pitt, strong as he was in the support of the great body of the nation, might easily have repressed the turbulence of the discontented minority by firmly yet temperately enforcing the ordinary law. Whatever vigour he showed during this unfortunate part of his life was vigour out of place and season. He was all feebleness and languor in his conflict with the foreign enemy who was really to be dreaded, and reserved all his energy and resolution for the domestic enemy who might safely have been despised.

One part only of Pitt's conduct during the last eight years of Irish the 18th century deserves high praise. He was the first English policy minister who formed great designs for the benefit of Ireland. The manner in which the Roman Catholic population of that unfortunate country had been kept down during many generations seemed to him unjust and cruel; and it was scarcely possible for a man of his abilities not to perceive that, in a contest against the Jacobins, the Roman Catholics were his natural allies. Had he been able to do all that he wished, it is probable that a wise and liberal policy would have averted the rebellion of 1798. But the difficulties which he encountered were great, perhaps insurmountable; and the Roman Catholics were, rather by his misfortune than by his fault, thrown into the hands of Jacobins. There was a third great rising of the Irishry against the Englishry, a rising not less formidable than the risings of 1641 and 1689. The Englishry remained victorious; and it was necessary for Pitt, as it had been necessary for Oliver Cromwell and William of Orange before him, to consider how the victory should be used. It is only just to his memory to say that he formed a scheme of policy so grand and so simple, so righteous and so humane, that it would alone entitle him to a high place among statesmen. He determined to make Ireland one kingdom with England, and, at the same time, to relieve the Roman Catholic laity from civil disabilities, and to grant a public maintenance to the Roman Catholic clergy. Had he been able to carry these noble designs into effect, the Union would have been a union indeed. It would have been inseparably associated in the minds of the great majority of Irishmen with civil and religious freedom; and the old parliament in College Green would have been regretted only by a small knot of discarded jobbers and oppressors, and would have been remembered by the body of the nation with the loathing and contempt due to the most tyrannical and the most corrupt assembly that had ever sat in Europe. But Pitt could execute only one half of what he had projected. He succeeded in obtaining the consent of the parliaments of both kingdoms to the Union; but that reconciliation of races and sects without which the Union could exist only in name was not accomplished. He was well aware that he was likely to find difficulties in the closet. But he flattered himself that, by cautious and dexterous management, those difficulties might be overcome. Unhappily, there were traitors and sycophants in high place who did not suffer him to take his own time and his own way, but prematurely disclosed his scheme to the king, and disclosed it in the manner most likely to irritate and alarm a weak and diseased mind. His Majesty absurdly imagined that his coronation oath bound him to refuse his assent to any bill for relieving Roman Catholics from civil disabilities. To argue with him was impossible. Dundas tried to explain the matter, but was told to keep his Scotch metaphysics to himself. Pitt and Pitt's ablest colleagues resigned their Resigns offices. It was necessary that the king should make a new arrangement. But by this time his anger and distress had brought March 16 back the malady which had, many years before, incapacitated him 1801. for the discharge of his functions. He actually assembled his family, read the coronation oath to them, and told them that, if he broke it, the crown would immediately pass to the house of Savoy. It was not until after an interregnum of several weeks that he regained the full use of his small faculties, and that a ministry after his own heart was at length formed.

The materials out of which he had to construct a Government were neither solid nor splendid. To that party, weak in numbers, but strong in every kind of talent, which was hostile to the domestic and foreign policy of his late advisers, he could not have recourse. For that party, while it differed from his late advisers on every point on which they had been honoured with his approbation, cordially agreed with them as to the single matter which had brought on them his displeasure. All that was left to him was to call up the rear ranks of the old ministry to form the front rank of a new ministry. In an age pre-eminently fruitful of parliamentary talents, a cabinet was formed containing hardly a single man who in parliamentary talents could be considered as even of the second rate. The most important offices in the state were bestowed on decorous and laborious mediocrity. Henry Addington was at the

Addington ministry.

head of the treasury. He had been an early, indeed a hereditary, friend of Pitt, and had by Pitt's influence been placed, while still a young man, in the chair of the House of Commons. He was universally admitted to have been the best Speaker that had sat in that chair since the retirement of Onslow. But nature had not bestowed on him very vigorous faculties; and the highly respectable situation which he long occupied with honour had rather unfitted than fitted him for the discharge of his new duties. His business had been to bear himself evenly between contending factions. He had taken no part in the war of words; and he had always been addressed with marked deference by the great orators who thundered against each other from his right and from his left. It was not strange that when, for the first time, he had to encounter keen and vigorous antagonists, who dealt hard blows without the smallest ceremony, he should have been awkward and unready, or that the air of dignity and authority which he had acquired in his former post, and of which he had not divested himself, should have made his helplessness laughable and pitiable. Nevertheless, during many months, his power seemed to stand firm. He was a favourite with the king, whom he resembled in narrowness of mind, and to whom he was more obsequious than Pitt had ever been. The nation was put into high good humour by a peace with France. The enthusiasm with which the upper and middle classes had rushed into the war had spent itself. Jacobinism was no longer formidable. Everywhere there was a strong reaction against what was called the atheistical and anarchical philosophy of the 18th century. Bonaparte, now first consul, was busied in constructing out of the ruins of old institutions a new ecclesiastical establishment and a new order of knighthood. That nothing less than the dominion of the whole civilized world would satisfy his selfish ambition was not yet suspected; nor did even wise men see any reason to doubt that he might be as safe a neighbour as any prince of the house of Bourbon had been. The treaty of Amiens was therefore hailed by the great body of the English people with extravagant joy. The popularity of the minister was for the moment immense. His want of parliamentary ability was, as yet, of little consequence; for he had scarcely any adversary to encounter. The old Opposition, delighted by the peace, regarded him with favour. A new Opposition had indeed been formed by some of the late ministers, and was led by Grenville in the House of Lords and by Windham in the House of Commons. But the new Opposition could scarcely muster ten votes, and was regarded with no favour by the country. On Pitt the ministers relied as on their firmest support. He had not, like some of his colleagues, retired in anger. He had expressed the greatest respect for the conscientious scruple which had taken possession of the royal mind; and he had promised his successors all the help in his power. In private his advice was at their service. In parliament he took his seat on the bench behind them, and in more than one debate defended them with powers far superior to their own. The king perfectly understood the value of such assistance. On one occasion, at the palace, he took the old minister and the new minister aside. "If we three," he said, "keep together, all will go well."

Relations between Pitt and Addington.

But it was hardly possible, human nature being what it is, and more especially Pitt and Addington being what they were, that this union should be durable. Pitt, conscious of superior powers, imagined that the place which he had quitted was now occupied by a mere puppet which he had set up, which he was to govern while he suffered it to remain, and which he was to fling aside as soon as he wished to resume his old position. Nor was it long before he began to pine for the power which he had relinquished. He had been so early raised to supreme authority in the state, and had enjoyed that authority so long, that it had become necessary to him. In retirement his days passed heavily. He could not, like Fox, forget the pleasures and cares of ambition in the company of Euripides or Herodotus. Pride restrained him from intimating, even to his dearest friends, that he wished to be again minister. But he thought it strange, almost ungrateful, that his wish had not been divined, that it had not been anticipated by one whom he regarded as his deputy.

Addington, on the other hand, was by no means inclined to descend from his high position. He was, indeed, under a delusion much resembling that of Abou Hassan in the Arabian tale. His brain was turned by his short and unreal caliphate. He took his elevation quite seriously, attributed it to his own merit, and considered himself as one of the great triumvirate of English statesmen, as worthy to make a third with Pitt and Fox.

Such being the feelings of the late minister and of the present minister, a rupture was inevitable; and there was no want of persons bent on making that rupture speedy and violent. Some of these persons wounded Addington's pride by representing him as a lacquey, sent to keep a place on the treasury bench till his master should find it convenient to come. Others took every opportunity of praising him at Pitt's expense. Pitt had waged a long, a bloody, a costly, an unsuccessful war. Addington had made peace. Pitt had suspended the constitutional liberties of Englishmen. Under Addington those liberties were again enjoyed. Pitt had wasted

the public resources. Addington was carefully nursing them. It was sometimes but too evident that these compliments were not unpleasing to Addington. Pitt became cold and reserved. During many months he remained at a distance from London. Meanwhile his most intimate friends, in spite of his declarations that he made no complaint, and that he had no wish for office, exerted themselves to effect a change of ministry. His favourite disciple, George Canning, young, ardent, ambitious, with great powers and great virtues, but with a temper too restless and a wit too satirical for his own happiness, was indefatigable. He spoke; he wrote; he intrigued; he tried to induce a large number of the supporters of the Government to sign a round robin desiring a change; he made game of Addington and of Addington's relations in a succession of lively pasquinades. The minister's partisans retorted with equal acrimony, if not with equal vivacity. Pitt could keep out of the affray only by keeping out of politics altogether; and this it soon became impossible for him to do. Had Napoleon, content with the first place among the sovereigns of the Continent, and with a military reputation surpassing that of Marlborough or of Turenne, devoted himself to the noble task of making France happy by mild administration and wise legislation, our country might have long continued to tolerate a Government of fair intentions and feeble abilities. Unhappily, the treaty of Amiens had scarcely been signed when the restless ambition and the insupportable insolence of the first consul convinced the great body of the English people that the peace so eagerly welcomed was only a precarious armistice. As it became clearer and clearer that a war for the dignity, the independence, the very existence of the nation was at hand, men looked with increasing uneasiness on the weak and languid cabinet which would have to contend against an enemy who united more than the power of Louis the Great to more than the genius of Frederick the Great. It is true that Addington might easily have made a better war minister than Pitt, and could not possibly have been a worse. But Pitt had cast a spell on the public mind. The eloquence, the judgment, the calm and disdainful firmness which he had during many years displayed in parliament deluded the world into the belief that he must be eminently qualified to superintend every department of politics; and they imagined, even after the miserable failures of Dunkirk, of Quiberon, and of the Helder, that he was the only statesman who could cope with Bonaparte. This feeling was nowhere stronger than among Addington's own colleagues. The pressure put on him was so strong that he could not help yielding to it; yet, even in yielding, he showed how far he was from knowing his own place. His first proposition was that some insignificant nobleman should be first lord of the treasury and nominal head of the administration, and that the real power should be divided between Pitt and himself, who were to be secretaries of state. Pitt, as might have been expected, refused even to discuss such a scheme, and talked of it with bitter mirth. "Which secretaryship was offered to you?" his friend Wilberforce asked. "Really," said Pitt, "I had not the curiosity to inquire." Addington was frightened into bidding higher. He offered to resign the treasury to Pitt, on condition that there should be no extensive change in the Government. But Pitt would listen to no such terms. Then came a dispute such as often arises after negotiations orally conducted, even when the negotiators are men of strict honour. Pitt gave one account of what had passed; Addington gave another; and, though the discrepancies were not such as necessarily implied any intentional violation of truth on either side, both were greatly exasperated.

Pitt declines subordinate office.

Meanwhile the quarrel with the first consul had come to a crisis. On the 16th of May 1803 the king sent a message calling on the House of Commons to support him in withstanding the ambitious and encroaching policy of France; and on the 22d the House took the message into consideration.

Pitt had now been living many months in retirement. There had been a general election since he had spoken in parliament, and there were two hundred members who had never heard him. It was known that on this occasion he would be in his place, and curiosity was wound up to the highest point. Unfortunately, the shorthand writers were, in consequence of some mistake, shut out on that day from the gallery, so that the newspapers contained only a very meagre report of the proceedings. But several accounts of what passed are extant; and of those accounts the most interesting is contained in an unpublished letter written by a very young member, John William Ward, afterwards earl of Dudley. When Pitt rose, he was received with loud cheering. At every pause in his speech there was a burst of applause. The peroration is said to have been one of the most animated and magnificent ever heard in parliament. "Pitt's speech," Fox wrote a few days later, "was admired very much, and very justly. I think it was the best he ever made in that style." The debate was adjourned; and on the second night Fox replied to it in an oration which, as the most zealous Pittites were forced to acknowledge, left the palm of eloquence doubtful. Addington made a pitiable appearance between the two great rivals; and it was observed that Pitt, while exhorting the Commons to stand resolutely by the executive Government

against France, said not a word indicating esteem or friendship for the prime minister.

War was speedily declared. The first consul threatened to invade England at the head of the conquerors of Belgium and Italy, and formed a great camp near the Straits of Dover. On the other side of those straits the whole population of our island was ready to rise up as one man in defence of the soil. At this conjuncture, as at some other great conjunctures in our history—the conjuncture of 1660, for example, and the conjuncture of 1688—there was a general disposition among honest and patriotic men to forget old quarrels, and to regard as a friend every person who was ready, in the existing emergency, to do his part towards the saving of the state. A coalition of all the first men in the country would, at that moment, have been as popular as the coalition of 1783 had been unpopular. Alone in the kingdom the king looked with perfect complacency on a cabinet in which no man superior to himself in genius was to be found, and was so far from being willing to admit all his ablest subjects to office that he was bent on excluding them all.

A few months passed before the different parties which agreed in regarding the Government with dislike and contempt came to an understanding with each other. But in the spring of 1804 it became evident that the weakest of ministries would have to defend itself against the strongest of Oppositions, an Opposition made up of three Oppositions, each of which would, separately, have been formidable from ability, and which, when united, were also formidable from number. The party which had opposed the peace, headed by Grenville and Windham, and the party which had opposed the renewal of the war, headed by Fox, concurred in thinking that the men now in power were incapable of either making a good peace or waging a vigorous war. Pitt had in 1802 spoken for peace against the party of Grenville, and had in 1803 spoken for war against the party of Fox. But of the capacity of the cabinet, and especially of its chief, for the conduct of great affairs, he thought as meanly as either Fox or Grenville. Questions were easily found on which all the enemies of the Government could act cordially together. The unfortunate first lord of the treasury, who had, during the earlier months of his administration, been supported by Pitt on one side and by Fox on the other, now had to answer Pitt and to be answered by Fox. Two sharp debates, followed by close divisions, made him weary of his post. It was known, too, that the Upper House was ever more hostile to him than the Lower, that the Scotch representative peers wavered, that there were signs of mutiny among the bishops. In the cabinet itself there was discord, and, worse than discord, treachery. It was necessary to give way; the ministry was dissolved, and the task of forming a Government was entrusted to Pitt.

Adding-
ton
ministry
resigns.

Pitt was of opinion that there was now an opportunity, such as had never before offered itself, and such as might never offer itself again, of uniting in the public service, on honourable terms, all the eminent talents of the kingdom. The passions to which the French Revolution had given birth were extinct. The madness of the innovator and the madness of the alarmist had alike had their day. Jacobinism and Antijacobinism had gone out of fashion together. The most liberal statesman did not think that season propitious for schemes of parliamentary reform; and the most conservative statesman could not pretend that there was any occasion for gagging bills and suspensions of the Habeas Corpus Act. The great struggle for independence and national honour occupied all minds; and those who were agreed as to the duty of maintaining that struggle with vigour might well postpone to a more convenient time all disputes about matters comparatively unimportant. Strongly impressed by these considerations, Pitt wished to form a ministry including all the first men in the country. The treasury he reserved for himself; and to Fox he proposed to assign a share of power little inferior to his own.

The plan was excellent; but the king would not hear of it. Dull, obstinate, unforgiving, and at that time half mad, he positively refused to admit Fox into his service. Anybody else, even men who had gone as far as Fox, or further than Fox, in what His Majesty considered as Jacobinism—Sheridan, Grey, Erskine—should be graciously received, but Fox never. During several hours Pitt laboured in vain to reason down this senseless antipathy. That he was perfectly sincere there can be no doubt; but it was not enough to be sincere—he should have been resolute. Had he declared himself determined not to take office without Fox, the royal obstinacy would have given way, as it gave way, a few months later, when opposed to the immutable resolution of Lord Grenville. In an evil hour Pitt yielded. He flattered himself with the hope that, though he consented to forego the aid of his illustrious rival, there would still remain ample materials for the formation of an efficient ministry. That hope was cruelly disappointed. Fox entreated his friends to leave personal considerations out of the question, and declared that he would support, with the utmost cordiality, an efficient and patriotic ministry from which he should be himself excluded. Not only his friends, however, but Grenville and Grenville's adherents answered with one voice that the question was not personal, that a great constitu-

tional principle was at stake, and that they would not take office while a man eminently qualified to render service to the commonwealth was placed under a ban merely because he was disliked at court. All that was left to Pitt was to construct a Government out of the wreck of Addington's feeble administration. The small circle of his personal retainers furnished him with a very few useful assistants, particularly Dundas (who had been created Viscount Melville), Lord Harrowby, and Canning.

Such was the inauspicious manner in which Pitt entered on his second administration. The whole history of that administration Pitt was of a piece with the commencement. Almost every month administration brought some new disaster or disgrace. To the war with France, there was soon added a war with Spain. The opponents of the ministry May 12 were numerous, able, and active. His most useful coadjutors he 1804. soon lost. Sickness deprived him of the help of Lord Harrowby. It was discovered that Lord Melville had been guilty of highly culpable laxity in transactions relating to public money. He was censured by the House of Commons, driven from office, ejected from the Privy Council, and impeached of high crimes and misdemeanours. The blow fell heavy on Pitt. It gave him, he said in parliament, a deep pang; and, as he uttered the word pang his lip quivered, his voice shook, he paused, and his hearers thought that he was about to burst into tears. Such tears shed by Eldon would have moved nothing but laughter. Shed by the warm-hearted and open-hearted Fox, they would have moved sympathy, but would have caused no surprise. But a tear from Pitt would have been something portentous. He suppressed his emotion, however, and proceeded with his usual majestic self-possession.

His difficulties compelled him to resort to various expedients. At one time Addington was persuaded to accept office with a peerage; but he brought no additional strength to the Government. Though he went through the form of reconciliation, it was impossible for him to forget the past. While he remained in place he was jealous and punctilious; and he soon retired again. At another time Pitt renewed his efforts to overcome his master's aversion to Fox; and it was rumoured that the king's obstinacy was gradually giving way. But, meanwhile, it was impossible for the minister to conceal from the public eye the decay of his health and the constant anxiety which gnawed at his heart. His sleep was broken. His food ceased to nourish him. All who passed him in the park, all who had interviews with him in Downing Street, saw misery written in his face. The peculiar look which he wore during the last months of his life was often pathetically described by Wilberforce, who used to call it the Austerlitz look.

Still the vigour of Pitt's intellectual faculties and the intrepid haughtiness of his spirit remained unaltered. He had staked everything on a great venture. He had succeeded in forming another mighty coalition against the French ascendancy. The united forces of Austria, Russia, and England might, he hoped, oppose an insurmountable barrier to the ambition of the common enemy. But the genius and energy of Napoleon prevailed. While the English troops were preparing to embark for Germany, while the Russian troops were slowly coming up from Poland, he, with rapidity unprecedented in modern war, moved a hundred thousand men from the shores of the ocean to the Black Forest, and compelled a great Austrian army to surrender at Ulm. To the first faint rumours of this calamity Pitt would give no credit. He was irritated by the alarms of those around him. "Do not believe a word of it," he said; "it is all a fiction." The next day he received a Dutch newspaper containing the capitulation. He knew no Dutch. It was Sunday, and the public offices were shut. He carried the paper to Lord Malmesbury, who had been minister in Holland; and Lord Malmesbury translated it. Pitt tried to bear up, but the shock was too great; and he went away with death in his face.

The news of the battle of Trafalgar arrived four days later, and seemed for a moment to revive him. Forty-eight hours after that most glorious and most mournful of victories had been announced to the country came the Lord Mayor's Day; and Pitt dined at Guildhall. His popularity had declined. But on this occasion the multitude, greatly excited by the recent tidings, welcomed him enthusiastically, took off his horses in Cheapside, and drew his carriage up King Street. When his health was drunk, he returned thanks in two or three of those stately sentences of which he had a boundless command. Several of those who heard him laid up his words in their hearts; for they were the last words that he ever uttered in public: "Let us hope that England, having saved herself by her energy, may save Europe by her example."

This was but a momentary rally. Austerlitz soon completed what Ulm had begun. Early in December Pitt had retired to Bath, in the hope that he might there gather strength for the approaching session. While he was languishing there on his sofa arrived the news that a decisive battle had been fought and lost in Moravia, that the coalition was dissolved, that the Continent was at the feet of France. He sank down under the blow. Ten days later he was so emaciated that his most intimate friends hardly knew him. He came up from Bath by slow journeys, and on the 11th of January 1806 reached his villa at Putney. Parlia-

ment was to meet on the 21st. On the 20th was to be the parliamentary dinner at the house of the first lord of the treasury in Downing Street; and the cards were already issued. But the days of the great minister were numbered. The only chance for his life, and that a very slight chance, was that he should resign his office, and pass some months in profound repose. His colleagues paid him very short visits, and carefully avoided political conversation. But his spirit, long accustomed to dominion, could not, even in that extremity, relinquish hopes which everybody but himself perceived to be vain. On the day on which he was carried into his bedroom at Putney the Marquis Wellesley, whom he had long loved, whom he had sent to govern India, and whose administration had been eminently able, energetic, and successful, arrived in London after an absence of eight years. The friends saw each other once more. There was an affectionate meeting and a last parting. That it was a last parting Pitt did not seem to be aware. He fancied himself to be recovering, talked on various subjects cheerfully and with an unclouded mind, and pronounced a warm and discerning eulogium on the marquis's brother Arthur. "I never," he said, "met with any military man with whom it was so satisfactory to converse." The excitement and exertion of this interview were too much for the sick man. He fainted away; and Lord Wellesley left the house convinced that the close was fast approaching.

And now members of parliament were fast coming up to London. The chiefs of the Opposition met for the purpose of considering the course to be taken on the first day of the session. It was easy to guess what would be the language of the king's speech, and of the address which would be moved in answer to that speech. An amendment condemning the policy of the Government had been prepared, and was to have been proposed in the House of Commons by Lord Henry Petty, a young nobleman who had already won for himself that place in the esteem of his country which, after the lapse of more than half a century, he still retains.¹ He was unwilling, however, to come forward as the accuser of one who was incapable of defending himself. Lord Grenville, who had been informed of Pitt's state by Lord Wellesley, and had been deeply affected by it, earnestly recommended forbearance; and Fox, with characteristic generosity and good nature, gave his voice against attacking his now helpless rival. "Sunt lacrymæ rerum," he said, "et mentem mortalia tangunt." On the first day, therefore, there was no debate. It was rumoured that evening that Pitt was better. But on the following morning his physicians pronounced that there were no hopes. The commanding faculties of which he had been too proud were beginning to fail. His old tutor and friend, the bishop of Lincoln, informed him of his danger, and gave such religious advice and consolation as a confused and obscured mind could receive. Stories were told of devout sentiments fervently uttered by the dying man. But these stories found no credit with anybody who knew him. Wilberforce pronounced it impossible that they could be true; "Pitt," he added, "was a man who always said less than he thought on such topics." It was asserted in many after-dinner speeches, Grub Street elegies, and academic prize poems and prize declamations that the great minister died exclaiming, "Oh my country!" This is a fable, but it is true that the last words which he uttered, while he knew what he said, were broken exclamations about the alarming state of public affairs. He ceased to breathe on the morning of the 23rd of January 1806, the twenty-fifth anniversary of the day on which he first took his seat in parliament. He was in his forty-seventh year, and had been during near nineteen years first lord of the treasury, and undisputed chief of the administration. Since parliamentary government was established in England, no English statesman has held supreme power so long. Walpole, it is true, was first lord of the treasury during more than twenty years, but it was not till Walpole had been some time first lord of the treasury that he could be properly called prime minister.

It was moved in the House of Commons that Pitt should be honoured with a public funeral and a monument. The motion was opposed by Fox in a speech which deserves to be studied as a model of good taste and good feeling. The task was the most invidious that ever an orator undertook; but it was performed with a humanity and delicacy which were warmly acknowledged by the mourning friends of him who was gone. The motion was carried by 288 votes to 89.

The 22d of February was fixed for the funeral. The corpse having lain in state during two days in the Painted Chamber, was borne with great pomp to the northern transept of the Abbey. A splendid train of princes, nobles, bishops, and privy councillors followed. The grave of Pitt had been made near to the spot where his great father lay, near also to the spot where his great rival was soon to lie. The sadness of the assistants was beyond that of ordinary mourners. For he whom they were committing to the

dust had died of sorrows and anxieties of which none of the survivors could be altogether without a share. Wilberforce, who carried the banner before the hearse, described the awful ceremony with deep feeling. As the coffin descended into the earth, he said, the eagle face of Chatham from above seemed to look down with consternation into the dark house which was receiving all that remained of so much power and glory.

All parties in the House of Commons readily concurred in voting forty thousand pounds to satisfy the demands of Pitt's creditors. Some of his admirers seemed to consider the magnitude of his embarrassments as a circumstance highly honourable to him; but men of sense will probably be of a different opinion. It is far better, no doubt, that a great minister should carry his contempt of money to excess than that he should contaminate his hands with unlawful gain. But it is neither right nor becoming in a man to whom the public has given an income more than sufficient for his comfort and dignity to bequeath to that public a great debt, the effect of mere negligence and profusion. As first lord of the treasury and chancellor of the exchequer Pitt never had less than six thousand a year, besides an excellent house. In 1792 he was forced by his royal master's friendly importunity to accept for life the office of warden of the Cinque Ports, with near four thousand a year more. He had neither wife nor child; he had no needy relations; he had no expensive tastes; he had no long election bills. Had he given but a quarter of an hour a week to the regulation of his household, he would have kept his expenditure within bounds. Or, if he could not spare even a quarter of an hour a week for that purpose, he had numerous friends, excellent men of business, who would have been proud to act as his stewards. One of those friends, the chief of a great commercial house in the city, made an attempt to put the establishment in Downing Street to rights, but in vain. He found that the waste of the servants' hall was almost fabulous. The quantity of butcher's meat charged in the bills was nine hundredweight a week. The consumption of poultry, of fish, of tea, was in proportion. The character of Pitt would have stood higher if with the disinterestedness of Pericles and of De Witt he had united their dignified frugality.

The memory of Pitt has been assailed, times innumerable, often *Estimates* justly, often unjustly; but it has suffered much less from his of Pitt assailants than from his eulogists. For, during many years, his name was the rallying cry of a class of men with whom, at one of those terrible conjunctures which confound all ordinary distinctions, he was accidentally and temporarily connected, but to whom, on almost all great questions of principle, he was diametrically opposed. The haters of parliamentary reform called themselves Pittites, not choosing to remember that Pitt made three motions for parliamentary reform, and that, though he thought that such a reform could not safely be made while the passions excited by the French Revolution were raging, he never uttered a word indicating that he should not be prepared at a more convenient season to bring the question forward a fourth time. The toast of Protestant ascendancy was drunk on Pitt's birthday by a set of Pittites who could not but be aware that Pitt had resigned his office because he could not carry Catholic emancipation. The defenders of the Test Act called themselves Pittites, though they could not be ignorant that Pitt had laid before George III. unanswerable reasons for abolishing the Test Act. The enemies of free trade called themselves Pittites, though Pitt was far more deeply imbued with the doctrines of Adam Smith than either Fox or Grey. The very negro-drivers invoked the name of Pitt, whose eloquence was never more conspicuously displayed than when he spoke of the wrongs of the negro. This mythical Pitt, who resembles the genuine Pitt as little as the Charlemagne of Ariosto resembles the Charlemagne of Eginhard, has had his day. History will vindicate the real man from calumny disguised under the semblance of adulation, and will exhibit him as what he was—a minister of great talents, honest intentions, and liberal opinions, pre-eminently qualified, intellectually and morally, for the part of a parliamentary leader, and capable of administering with prudence and moderation the government of a prosperous and tranquil country, but unequal to surprising and terrible emergencies, and liable in such emergencies to err grievously, both on the side of weakness and on the side of violence. (M.)

PITTA, in Ornithology, from the Telegu *Pitta*, meaning a small Bird, Latinized by Vieillot in 1816 (*Analyse*, p. 42) as the name of a genus, and since adopted by English ornithologists as the general name for a group of Birds, called by the French *Brèves*, and remarkable for their great beauty.² For a long while the Pittas were commonly supposed to be allied to the *Turdidæ*, and some English

¹ [Henry Petty Fitzmaurice, third marquis of Lansdowne, was born in London, July 2, 1780, and died at Bowood, January 31, 1863. He entered parliament in 1801, and succeeded to the peerage in 1809. For a brief period in 1828 he was secretary of state for the home department, and again, in 1828–29, secretary for foreign affairs. From 1831 to 1841, and from 1846 to 1852, he was lord president of the council.]

² In Ornithology the word is first found as part of the native name, "Pon-nunkya pitta," of a Bird, given in 1718 by Peltier, in the "Mantissa" to Ray's *Synopsis* (p. 195), on the authority of Buckley (see ORNITHOLOGY, vol. xviii, p. 6, note 1). This bird is the *Pitta bengalensis* of modern ornithologists, and is said by Jerdon (*Birds of India*, 1. p. 503) now to bear the Telegu name of *Pona-inkit*.

funeral.

writers applied to them the name of "Water-Thrushes" and "Ant-Thrushes," though there was no evidence of their having aquatic habits or predilections, or of their preying especially upon ants; but the fact that they formed a separate Family was gradually admitted. Their position was at last determined by Garrod, who, having obtained examples for dissection, in a communication to the Zoological Society of London, printed in its *Proceedings* for 1876, proved (pp. 512, 513) that the *Pittidæ* belonged to that section of Passerine Birds which he named *Mesomyodi* (ORNITHOLOGY, vol. xviii. p. 41), since their syrinx, like that of the *Tyrannidæ* (KING-BIRD, vol. xiv. p. 80), has its muscles attached to the middle of its half-rings, instead of to their extremities as in the higher Passerines or *Acromyodi*. This in itself was an unexpected determination, for such a structure had been thought to be confined to Birds of the New World, to which none of the Pittas belong. But it is borne out by, and may even serve to explain, the sporadic distribution of the latter, which seems to point them out as survivors of a somewhat ancient and lower type of *Passeres*. Indeed except on some theory of this kind the distribution of the Pittas is almost unaccountable. They form a very homogeneous

Pitta elegans, male and female.

Family, not to say genus, which it is not easy to split up justifiably, for all its members bear an unmistakable and close resemblance to each other—though the species inhabit countries so far apart as Angola and China, India and Australia; and, to judge from the little that has been recorded, they are all of terrestrial habit, while their power of flight, owing to their short wings, is feeble. Nearly fifty species have now been described, most of them found in the Malay Archipelago, between the eastern and western divisions of which they are pretty equally divided; and, in Mr Wallace's opinion,¹ they attain their maximum of beauty and variety in Borneo and Sumatra, from the latter of which islands comes the species, *Pitta elegans*, represented in the accompanying woodcut. Few Birds can vie with the Pittas in brightly-contrasted coloration. Deep velvety black, pure white, and intensely vivid scarlet, turquoise-blue and beryl-green—mostly occupying a considerable extent of surface—are found in a great many of the species,—to say nothing of other composite or intermediate hues; and, though in some a modification of these tints is observable, there is scarcely a trace of any blending of shade, each patch of colour standing out distinctly.

¹ Owing to recent discoveries in Papuasia it is possible that this opinion may require some modification.

This is perhaps the more remarkable as the feathers have hardly any lustre to heighten the effect produced, and in some species the brightest colours are exhibited by the plumage of the lower parts of the body. Pittas vary in size from that of a Jay to that of a Lark, and generally have a strong bill, a thickset form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little or no external difference between the sexes. All the species then known were figured in Mr Elliot's *Monograph of the Pittidæ*, completed in 1863; but so many have since been described that this work but imperfectly represents the existing knowledge of the Family, and even Schlegel's revised catalogue of the specimens contained in the Leyden Museum (*Mus. des Pays-Bas*, livr. 11), published in 1874, is now out of date, so that a new synopsis is very desirable. Many of the lately-discovered species have been figured in Gould's *Birds of Asia* and *Birds of New Guinea*.

Placed by some authorities among the *Pittidæ* is the genus *Philepitta*, consisting of two species peculiar to Madagascar, while other systematists would consider it to form a distinct Family. This last is the conclusion arrived at by W. A. Forbes (*Proc. Zool. Society*, 1880, pp. 387–391) from its syringeal characters, which, though shewing it to be allied to the Pittas, are yet sufficiently different to justify its separation as the type of a Family *Philepittidæ*. The two species which compose it have little outward resemblance to the Pittas, not having the same style of coloration and being apparently of more arboreal habits. The sexes differ greatly in plumage, and the males have the skin round the eyes bare of feathers and carunculated.

It may be advisable to remark that nomenclatorial purists, objecting to the names *Pitta* and *Philepitta* as "barbarous," call the former *Coloburis* and the latter *Paictes*. *Brachyurus* also has frequently been used for *Pitta*; but, having been previously applied in another sense, it is inadmissible. (A. N.)

PITTACUS of Mytilene in Lesbos, one of the seven sages of Greece, was born in 651 B.C. His father Hyrradius (or Caicus) was a Thracian, his mother was a Lesbian. About 611 B.C. Pittacus, along with the brothers of the poet Alcæus, overthrew Melanchrus, tyrant of Lesbos. In a war between the Mytilenians and Athenians for the possession of the town of Sigeum on the Hellespont, Pittacus, as general of the Mytilenians, slew the Athenian commander Phrynon in single combat, having entangled him in a net (606 B.C.). In 589 his fellow-citizens entrusted Pittacus with despotic power for the purpose of protecting them against the exiled nobles, at the head of whom were Alcæus and Antimenides. Pittacus effected this object, and, without introducing a new constitution, contrived by legislation to restore the existing constitution to regular working order. One of his laws enacted that offences committed during intoxication should be punished with double severity. For the historian of the law of inheritance some interest attaches to the enactment of Pittacus that father and mother should succeed, in equal shares, to the property of a deceased child. He resigned the government after holding it for ten years, and died ten years later (569 B.C.).

The stories which bring Pittacus and Croesus into connexion are probably mere legend, since Croesus was only twenty-five years of age at the date of Pittacus's death. Pittacus was regarded as a pattern of all the virtues, and this high character is borne out by what we know of him. When Alcæus, who had bitterly assailed him in his poems, fell into his hands, he let him go, saying that forgiveness was better than revenge. Of the lands which his grateful countrymen would have bestowed on him he accepted only a small part. Amongst the sayings attributed to him are these:—it is hard to be good; rule reveals the man; the best rule is that of law; speak ill neither of friend nor foe. Pittacus was also a poet; Diogenes Laertius states that he composed six hundred elegiac verses.

PITTSBURGH, the second largest city of Pennsylvania, and the leading iron, steel, and glass manufacturing centre of the United States, lies at the confluence of the Allegheny and the Monongahela, which unite here to form the Ohio, 250 miles west by north of Philadelphia. The business quarter of the city is built on a nearly level triangular plain, between the two rivers, measuring about three quarters of a mile on each side back to the hills which rise to the east.

The manufacturing establishments stretch for a distance of 7 miles up the Allegheny, 7 up the Monongahela, and 2 down the Ohio, and occupy the strip of low ground usually a few hundred feet broad between the river banks and the hills which generally face them. The slope of the hills to the east of the business quarter is closely built with residences and retail stores for the distance of a mile and a half, but the summits, 400 or 500 feet high, are partially unoccupied. Beyond the hills extends a rolling country which, for a space of about 5 miles long by 2 wide is occupied by the villas of the citizens. The hills facing the rivers are generally precipitous, and vary in height from 300 to 600 feet, but at different points they recede from the river banks and afford sites for the

the city is obtained from a view of the suburban quarters of the East End and the parks and residence quarters of Allegheny. And, all disfigurement and dirtiness notwithstanding, it is full of interesting and striking sights. The interiors of its rolling-mills and glass-houses, and the views of the city from the surrounding hills, with the manufacturing quarters marked out by their smoke by day and their fires by night, are of a unique and picturesque character. Along the rivers are fleets of steamers towing barges laden with coal for consumption at this point and for shipment to the cities lower down. Joining the various quarters of the city are ten bridges for ordinary traffic and four railway viaducts, among which the Point Bridge and the Smithfield Street Bridge are fine examples of engineering in iron. Six inclined-plane railways afford access to the summits of the high hills.

Pittsburgh is of historical interest from the struggle (1755-1758) for its possession between England and France in the Seven Years' War, and the fact that the public and military career of George Washington was commenced with those campaigns (see WASHINGTON). With the termination of that struggle in the capture of the ruins of Fort Duquesne by the British, the history of the place becomes that of an ordinary frontier town. A new fort was erected and named Fort Pitt in honour of the prime minister whose energy had urged the war forward to its capture, and wrested the Ohio valley and Canada from French control. After one or two Indian wars, in which the post was threatened, and on one occasion nearly taken, Fort Pitt lost its military character and became a trading town. The first streets were laid out near the fort in 1764, and in 1769 the first survey of the unsettled lands in the vicinity was made for the proprietors, the heirs of William Penn, under the name of the manor of Pittsburgh. After the termination of the revolution, the legislature of Pennsylvania incorporated Pittsburgh as a village on April 22, 1794, and on March 18, 1816, its charter as a city was granted. During the colonial period a dispute arose between Virginia and Pennsylvania as to the possession of the territory surrounding the town, and in the first few years of its history under the United States it attracted attention from its proximity to the famous "Whisky Insurrection" of Western Pennsylvania. After it had attained a population of 30,000 it was visited on the 10th of April 1845 by a disastrous conflagration in which the buildings in the business centre, covering a space of 56 acres, and valued at \$5,000,000 dollars, were consumed.

Plan of Pittsburgh.

suburbs of Lawrenceville (on the Allegheny), Hazlewood, and Birmingham (on the north and south banks respectively of the Monongahela), which are within the municipality of Pittsburgh, and (on the north bank of the Allegheny and Ohio) for the city of Allegheny, which, with its separate municipal government and population of 78,000 inhabitants, is commercially and socially a part of Pittsburgh. The two cities together cover an irregular space of 9 miles between the extreme eastern and western points, with a breadth varying from 2 to 4 miles.

From the character of its site Pittsburgh would naturally be very attractive, but the free use of the bituminous coal which has been the principal agent in its development has so spoiled its beauty as to give it the name of the Smoky City. Not only do the manufacturing quarters show long lines of smoke-stained buildings, but the business quarter, which is composed of rather narrow streets laid out early in the century, is mainly constructed of brick and iron, and in spite of the presence of some fine public buildings in granite and brown stone—the municipal hall, the petroleum exchange, the new United States post office and court-house (1884), the new county court-house (1884), &c.—has a generally grimy and unattractive appearance. A better opinion of the wealth and taste of

besides names of streets, hills, and suburbs to recall the struggle which decided the Anglo-Saxon character of the country. The locality known as the Point, where Fort Duquesne stood, is covered with thickly built factories and dingy tenements. In a squalid and obscure court a portion of the wall of a blockhouse erected in 1763 by Colonel Boquet, one of the British commandants of Fort Pitt, still forms a part of a building, and on the wall of the staircase of Municipal Hall is a stone bearing the inscription with which that officer commemorated its erection. Immediately across the Monongahela a range of precipitous hills some 500 feet high bears the names of Mount Washington and Duquesne Heights. On the first hill rising to the east of the level part of the city, a red granite court-house, to cost \$2,000,000, is in process of construction near to the spot where Major Grant was defeated and slain, and the new building will replace the brown stone structure which for many years fronted on the street bearing that unfortunate officer's name. Twelve miles away, the suburb long known as Braddock's Field and now as Braddock's, attracts attention chiefly by the roar and glare of its great steel manufacturing establishment.

Deriving its early importance in commerce from its position at the head of the Ohio, which was until 1855 the principal route between the middle States and the west and south-west, Pittsburgh has since obtained its greatest growth from the coal which underlies nearly all Western Pennsylvania. This has made the city and its immediate suburbs the most important manufacturing district in America, in both pig and bar iron, steel, glass, and copper. In 1883 Allegheny county produced 11½ per cent. of the pig iron produced in the United States, and 21 per cent. of the rolled iron and steel. The iron industry consists of 16 blast furnaces, producing, in 1883, 592,475 tons; 32 rolling mills, producing 472,351

tons of finished iron; and 91 other establishments, turning out a large variety of other manufactures of iron, from boilers to safes and steam pumps. The steel industry comprises 20 large mills with an output for 1883 of 405,530 tons. The blast furnaces and rolling-mills of Pittsburgh employ a capital of \$23,910,000 and 21,190 workmen, the steel industry \$10,170,000 and 7060 workmen. Next in importance is the glass manufacture, in which 75 establishments are engaged, 24 making table ware, 24 window glass, 10 green glass bottles, and 9 lamp chimneys. The capital invested in them is \$5,985,000. They employ 6442 hands, and the value of their last reported annual production is \$6,832,683. The coal and coke industry of the district, which is controlled mainly by Pittsburgh, comprises a capital of \$26,406,500, employs 23,621 miners and other labourers, and makes an annual output of 7,720,000 tons of coal and 2,760,000 tons of coke, valued at \$16,600,000. The total of all the manufacturing industries of the city is 1380 establishments, with \$105,401,481 of capital, employing 85,936 workmen of all kinds, and producing to the value of \$149,721,619. The wholesale trade of the city is much less important than its manufacturing industries, and with a few exceptions is confined to the immediate vicinity. It includes 90 firms with an aggregate capital of \$11,206,000 and total sales of \$125,390,472. Within the last year a new and unique industry has been developed. By drilling in the earth to a depth of 1200 to 2000 feet, what is practically the fire-damp of the coal mine is tapped in such quantity that it comes to the surface in great force. It has been found to be useful as a fuel for all the purposes of coal except the smelting of ores in blast furnaces; and, as it is cheaper both for making steam and for the heating of the iron and glass furnaces, its adoption has been general among the manufacturers.

As the railway system has developed, the important boating interest of Pittsburgh has become confined to the transportation of coal from the Monongahela river mines to the down-river cities. The coal is only taken out when freshets have raised the river, and at that time fleets of steamers, each towing from eight to fifteen barges, covering acres in extent and carrying thousands of tons of coal, start down stream. The total steam tonnage of Pittsburgh is 36,845 tons with 163 vessels, but the addition of the barges brings the tonnage up to 1,359,972 and the number of vessels to 3208.

Pittsburgh is stated to be the origin of more railway freight than any other point in the country. There are a large number of lines, under the control of three great companies. The most important is the Pennsylvania Railroad, whose trunk lines pass through the city, and number among their feeders the West Pennsylvania; the Allegheny Valley; the Pittsburgh, Virginia, and Charleston; the Pittsburgh, Cincinnati, and St Louis; the Pittsburgh, Fort Wayne, and Chicago; and the Cleveland and Pittsburgh Railroads. The Pittsburgh division of the Baltimore and Ohio Railroad gives a connexion with that trunk line, and by the Pittsburgh and Western, and the Pittsburgh, Cleveland, and Toledo, reaches the Chicago branch of the same system to the west. The Pittsburgh and Lake Erie affords the New York Central and the New York, Pennsylvania, and Ohio lines an access to Pittsburgh, while its extension under the name of the Pittsburgh, McKeesport, and Youghiogheny penetrates the coal and coke district to the south-east.

In 1796, by the first accurate census on record, the population of Pittsburgh was 1395. By 1810 it had increased to 4968; by 1820 to 7248; by 1830 to 12,452; by 1840 to 21,115; by 1850 to 36,601; by 1860 to 49,221; by 1870 to 86,076. In 1874 the consolidation of outlying boroughs made the population, according to the census of 1870, 121,799; and in 1880 this had increased to 156,389. These figures do not comprise the population of Allegheny, which was 28,702 in 1860, 53,180 in 1870, and 78,682 in 1880. Including the manufacturing and residential suburbs, the total population by the census of 1880 was 274,160; and, with the large extension of manufacturing and building that has gone on since then, it was estimated in 1884 at 325,000.

The municipal governments of Pittsburgh and Allegheny are each composed of a mayor, controller, and treasurer, with city councils in two branches styled respectively select and common. These are elected by the people, and appoint other administrative officials to take charge of the police and fire departments, assessments, and public works. The total assessed valuation of the city of Pittsburgh for purposes of taxation is \$101,508,603, on which a revenue is collected for all purposes of \$2,777,405. Allegheny has an assessed valuation of \$40,707,858, and spends \$650,000 annually. The total indebtedness of Pittsburgh is \$14,497,800, of which nearly \$10,000,000 was expended for water-works and street pavements. The debt of Allegheny is but \$1,400,000.

The school system of each city is governed by a central board of education and ward boards, both elected by popular vote. The Pittsburgh system comprises a fine stone high school overlooking the city, and 52 ward schools, in which are 469 teachers and 23,629 scholars, the approximate annual expenditure being \$550,000. In the Allegheny system there are the high school

and 18 ward schools, with 207 teachers, 9392 scholars, and an annual expenditure of about \$200,000. The principal institutions established by public taxation are the Riverside State Penitentiary, completed in 1884 in the lower part of Allegheny; the Morganza Reform School; the workhouse at Claremont, on the Allegheny river; and the Pittsburgh, Allegheny, and County poorhouses.

The churches and chapels in Pittsburgh and Allegheny number 237: 57 are Roman Catholic, including 13 monastic and conventual establishments; 53 represent the various branches of Presbyterianism; 39 are Methodist Episcopal, and 16 Protestant Episcopal. Among the leading examples of church architecture are St Paul's Cathedral (Roman Catholic), Trinity and St Peter's (Protestant Episcopal), the First and Third Presbyterian and the German Lutheran churches in Pittsburgh, and the North Presbyterian in Allegheny. Private charity has established the West Penn. Hospital with a large branch for the treatment of the insane at Dixmont, the Homeopathic Hospital, the Mercy Hospital, the Pittsburgh Infirmary, the Free Dispensary, the North Side Hospital, and St Francis Hospital; and 18 asylums for orphans and the aged and infirm are maintained throughout the two cities. The collegiate institutions comprise the Western University, the Western Theological Seminary (Presbyterian), the United Presbyterian Seminary, the Catholic College, the Pennsylvania Female College, and the Pittsburgh Female College. (J. F. H.)

PITTSFIELD, a borough and township of the United States, the shire town of Berkshire county, Massachusetts, lies at a height of from 1000 to 1200 feet above the sea on a plain between the Hoosacs on the east and the Taconics on the west. It is traversed by the headwaters of the Housatonic and Hoosac rivers, and derives its supply of drinking water from Lake Ashley, a romantic loch on the top of the Washington Hills, 7 miles to the south-east. As the northern terminus of the Housatonic Railroad, and a junction on the Boston and Albany and the Pittsfield and North Adams Railroads, it is an important centre of traffic. Most of the dwelling houses are built of wood. Among the public edifices are a court-house, in white marble; the Berkshire Athenæum, with a free library and reading-room; the Roman Catholic church of St Joseph, in marble; the Methodist church, a spacious edifice of brick; the First Congregational church (rebuilt in 1853), for thirty years under the charge of Rev. John Todd, author of the *Student's Manual*; and the Maplewood Institute for young ladies. The Berkshire Medical Institute (1822) ceased to exist in 1869. There is a small park with a fine soldiers' monument (1872) in the heart of the town, as well as a larger park with a race-course in the eastern suburb. Cotton and woollen goods, silk, knit goods, shoes, and tacks are among the local manufactures. The population in 1860 was 8045; in 1870, 11,132; in 1880, 13,364. Pittsfield, which once formed part of the Indian domain of Pontoosuc, and for a time was known as Boston Plantation, was incorporated in 1761, and received its present name in honour of the earl of Chatham. Oliver W. Holmes long resided on a small farm two miles south of Pittsfield.

PITTSTON, a borough of the United States, in Luzerne county, Pennsylvania, on the east bank of the Susquehanna, just below the confluence of the Lackawanna, 105 miles north by west of Philadelphia. It is the centre of the Wyoming anthracite region and the seat of the Pennsylvania Coal Company's operations, contains knitting mills, planing mills, terra cotta works, a stove factory, lumber yards, &c., and commands four distinct railway lines. The population was 6760 in 1870 and 7472 in 1880. If West Pittston (a borough on the other side of the Susquehanna, with which Pittston communicates by two bridges) were included, the total would be 10,016.

PIUS I. Hardly anything is known with certainty respecting Pius I., except that he was bishop of Rome from 158 to 167 A.D. He is said to have been born at Aquileia and to have been the son of a certain Rufinus; it is added that he suffered martyrdom, but, although

he is celebrated as a martyr in the breviary, there seems no other evidence for this assertion. A few letters extant under his name are spurious.

PIUS II. (Enea Silvio Piccolomini, commonly known in literature as Æneas Sylvius), pope from 1458 to 1464, "whose character reflects almost every tendency of the age in which he lived," was born at Corsignano in the Sienese territory, October 18, 1405, of a noble but decayed family. After studying at the universities of Siena and Florence, he settled in the former city as a teacher, but in 1431 accepted the post of secretary to Domenico Capranica, bishop of Fermo, then on his way to Basel to protest against the injustice of the new pope Eugenius IV. in refusing him the cardinalate for which he had been designated by Martin V. Arriving at Basel after numerous adventures, he successively served Capranica and several other masters. In 1435 he was sent by Cardinal Albergata, Eugenius's legate at the council, on a secret mission to Scotland, the object of which is variously related, even by himself. He visited England as well as Scotland, underwent many perils and vicissitudes in both countries, and has left a valuable account of each. Upon his return he sided actively with the council in its conflict with the pope, and, although still a layman, obtained a leading share in the direction of its affairs. But when in 1442 the council elected Amadeus, duke of Savoy, as an antipope under the name of Felix V., Æneas, perceiving that the step was generally disapproved, found a pretext for withdrawing to the emperor Frederick III.'s court at Vienna. He was there crowned imperial poet laureate, and obtained the patronage of the emperor's chancellor, Kaspar Schlick, a love adventure of whose at Siena he celebrated in his romance, *Eurialus and Lucretia*. His character had hitherto been that of an easy man of the world, with no pretence to strictness in morals or consistency in politics. He now began to be more regular in the former respect, and in the latter adopted a decided line by making his peace with Rome. Being sent on a mission to Rome in 1445, with the ostensible object of inducing Eugenius to convoke a new council, he was absolved from ecclesiastical censures, and returned to Germany under an engagement to assist the pope. This he did most effectually by the diplomatic dexterity with which he smoothed away differences between the court of Rome and the German electors; and he had a leading part in the compromise by which, in 1447, the dying Eugenius accepted the reconciliation tendered by the German princes, and the council and the antipope were left without support. He had already taken orders, and one of the first acts of Eugenius's successor Nicholas V. was to make him bishop of Trieste. In 1450 he was sent ambassador by the emperor Frederick to negotiate his marriage with the Princess Leonora of Naples, which object he successfully achieved; in 1451 he undertook a mission to Bohemia, and concluded a satisfactory arrangement with the Hussite chief George Podiebrad; in 1452 he accompanied Frederick to Rome, where the emperor wedded Leonora and was crowned king of the Romans. In August 1455 Æneas again arrived in Rome on an embassy to proffer the obedience of Germany to the new pope, Calixtus III. He brought strong recommendations from the emperor and King Ladislaus of Hungary for his nomination to the cardinalate, but delays arose from the pope's resolution to promote his own nephews first, and he did not attain the object of his ambition until December in the following year.

Calixtus III. died on August 6, 1458. On August 10 the cardinals entered into conclave. The wealthy cardinal of Rouen, though a Frenchman and of exceptional character, seemed certain to be elected. Æneas has told us in a passage of his own history of his times, long

retrenched from that work but printed clandestinely in the *Conclavi de' Pontifici Romani*, by what art, energy, and eloquence he frustrated this false step. It seemed but meet that the election should fall upon himself: no other candidate appears to have been seriously thought of; nor, although the sacred college probably included a few men of higher moral standard, had it any on the whole so worthy of the tiara. It was the peculiar faculty of Æneas to accommodate himself perfectly to whatever position he might be called upon to occupy; it was his peculiar good fortune that every step in life had placed him in circumstances appealing more and more to the better part of his nature, an appeal to which he had never failed to respond. The party pamphleteer had been more respectable than the private secretary, the diplomatist than the pamphleteer, the cardinal than the diplomatist; now the unscrupulous adventurer and licentious novelist of a few short years ago seated himself quite naturally in the chair of St Peter, and from the resources of his versatile character produced without apparent effort all the virtues and endowments becoming his exalted station. After allying himself with Ferdinand, the Aragonese claimant of the throne of Naples, his next important act was to convene a congress of the representatives of Christian princes at Mantua for joint action against the Turks. His long progress to the place of assembly resembled a triumphal procession; and the congress, a complete failure as regarded its ostensible object, at least showed that the impotence of Christendom was not owing to the pope. On his return from the congress Pius spent a considerable time in his native district of Siena, and has described his delight and the charms of a country life in very pleasing language. He was recalled to Rome by the disturbances occasioned by Tiburzio de Maso, who was ultimately seized and executed. The papal states were at this time greatly troubled by rebellious barons and marauding condottieri, but these evils gradually abated. The Neapolitan war was also terminated by the success of the pope's ally Ferdinand. In July 1461 Pius canonized St Catherine of Siena, and in October of the same year he gained what at first appeared to be a most brilliant success by inducing the new king of France, Louis XI., to abolish the pragmatic sanction, by which the pope's authority in France had been grievously impaired. But Louis had expected that Pius would in return espouse the French cause in Naples, and when he found himself disappointed he virtually re-established the pragmatic sanction by royal ordinances. Pius was also engaged in a series of disputes with the Bohemian king and the count of Tyrol, and the crusade for which the congress of Mantua had been convoked made no progress. The pope did his best: he addressed an eloquent letter to the sultan urging him to become a Christian; he succeeded in reconciling the emperor and the king of Hungary, and derived great encouragement as well as pecuniary advantage from the discovery of mines of alum in the papal territory. But France was estranged; the duke of Burgundy broke his positive promise; Milan was engrossed with the attempt to seize Genoa; Florence cynically advised the pope to let the Turks and the Venetians wear each other out. Pius was unawares nearing his end, and his malady probably prompted the feverish impatience with which on June 18, 1464, he assumed the cross and departed for Ancona to conduct the crusade in person. It seemed certain that the issue of such an enterprise could only be ridiculous or disastrous. Pius II.'s good genius again stepped in, and rendered it pathetic. He was suffering from fever when he left Rome. The crusading army melted away at Ancona for want of transport, and when at last the Venetian fleet arrived the dying pope could only view it from a window. He expired two days afterwards, August.

14, 1464, in his death as in his life a figure picturesque and significant far beyond the wont of Roman pontiffs. He was succeeded by Paul II.

Pius, indeed, regarded as a man and not merely as an historical personage, is the most interesting of all the successors of St Peter. It is easy to take his character to pieces, but the aroma of something exquisite lingers around every fragment. He had a healthy, sincere, loving nature, frank and naive even in his aberrations and defects, which seem after all sufficiently venial. The failings of other popes have most frequently been those of the priest, and therefore in the true sense of the term inhuman. It is a refreshing transition to the faults of the adventurer, the diplomatist, the man of letters and pleasure. The leading trait of Pius's character was his extreme impressionableness. Chameleon-like he took colour from surrounding circumstances, and could always depend on being what these circumstances required him to be. As, therefore, his prospects widened and his responsibilities deepened, his character widened and deepened too; and he who had entered upon life a shifty adventurer quitted it a model chief shepherd. His virtues were not only great, but the most conspicuous were those especially characteristic of the finer natures. While he vied with any man in industry, prudence, wisdom, and courage, he excelled most men in simplicity of tastes, constancy of attachments, kindly playfulness, magnanimity, and mercy. As chief of the church he was able and sagacious, and showed that he comprehended the conditions on which its monopoly of spiritual power could for a season be maintained; his views were far-seeing and liberal; and he was but slightly swayed by personal ends. He is especially interesting as the type of the scholar and publicist who wins his way by intellectual strength, foreshadowing the age to come when the pen should be mightier than the sword; and no less as the figure in whom the mediæval and the modern spirit are most distinctly seen to meet and blend, ere the latter definitively gains the mastery.

Pius was a versatile and voluminous author, one of the best and most industrious of his period. His most important work is his *Commentaries of his own Times*, published in 1584 under the name of Gobelinus, to whom it has been ascribed, but who was in fact only the copyist. It appears to have been altered to some slight extent by his secretary Campanus. Numerous passages suppressed at the time of publication have been recently published in the *Transactions* of the Accademia de' Lincei by Signor Cugnone, together with other inedited works. Pius's *Commentaries* are delightful reading, and their historical value is very great. "Pius II.," says Creighton, "is the first writer who attempted to represent the present as it would look to posterity, who consciously applied a scientific conception of history to the explanation and arrangement of passing events." His *Epistles*, which were collected by himself, are also an important source of historical information. The most valuable of his minor historical writings are his histories of Bohemia and of the emperor Frederick III., the latter partly autobiographical. He sketched geographical treatises on Europe and Asia, and in early and middle life produced numerous tracts on the political and theological controversies of his day, as well as on ethical subjects. Pius was greatly admired as a poet by his contemporaries, but his reputation in belles lettres rests principally upon his *Eurialus* and *Lucretia*, which continues to be read to this day, partly from its truth to nature, and partly from the singularity of an erotic novel being written by a pope. He also composed some comedies, one of which alone is extant, and as yet only in MS. All these works are in Latin. Pius was not an eminent scholar: his Latin is frequently incorrect, and he knew little Greek; but his writings have high literary qualities, and will always be prized as vivid and accurate reproductions of the spirit of a very remarkable age.

All the chief authorities for Pius's life are sifted and condensed in the admirable biography by Voigt (3 vols., Berlin, 1856-63). Professor Creighton, in his masterly *History of the Papacy during the Reformation* (vol. II., London, 1882), has given the English reader the substance of Voigt's narrative, while preserving a full independence of judgment. (R. G.)

PIUS III. (Francesco Todeschini), pope from September 22 to October 18, 1503, was born at Siena, May 9, 1439. As the nephew of Pius II. by his sister Laodamia, he was

received into favour by that pontiff, who permitted him to assume the name and arms of the Piccolomini, and raised him, when only twenty-two years of age, to the see of Siena and the cardinalate. He was employed by subsequent popes in several important legations, as by Paul II. at the diet of Ratisbon, and by Sixtus IV. to secure the restoration of ecclesiastical authority in Umbria. Amid the disturbances consequent upon the death of Alexander VI. he was, by the not wholly disinterested influence of Cardinal Rovera, elected pope on September 22, 1503, his installation taking place on the 8th October following. He at once took in hand the reform of the papal court and arrested Cæsar Borgia; but after a brief pontificate of twenty-six days he died (October 18, 1503) of an ulcer in the leg, or, as some have alleged, of poison administered at the instigation of Pandolfo Petrucci, governor of Siena. He was succeeded by Julius II.

PIUS IV. (Giovanni Angelo Medici), pope from 1559 to 1565, was born of humble parentage at Milan, March 31, 1499. His early career connects itself in some measure with the romantic rise of his elder brother from the position of bravo to that of Marchese di Marignano. After studying at Bologna and acquiring reputation as a jurist, he went in 1527 to Rome, and as the favourite of Paul III. was rapidly promoted to the governorship of several towns, the archbishopric of Ragusa, the vice-legateship of Bologna, and in April 1549 to the cardinalate. On the death of Paul IV. he was elected pope on December 28, 1559, and installed on the 6th January 1560. His first public acts of importance were to grant a general pardon to the participators in the riot which had closed the previous pontificate, and to bring to trial the nephews of his predecessor, of whom Cardinal Carlo Caraffa was strangled, and the duke Paliano, with his nearest connexions, beheaded. On the 18th January 1562 the council of Trent, which had been suspended by Julius III., was opened for the third time. Great skill and caution were necessary to effect a settlement of the questions before it, inasmuch as the three principal nations taking part in it, though at issue with regard to their own special demands, were prepared to unite their forces against the demands of Rome. Pius, however, aided by Morone and Borromeo, proved himself equal to the emergency, and by judicious management and concession brought the council to a termination satisfactory to the disputants and favourable to the pontifical authority. Its definitions and decrees were confirmed by a bull dated January 26, 1564; and, though they were received with certain limitations by France and Spain, the famous Creed of Pius IV., or Tridentine Creed, remained the authoritative expression of the Catholic faith. The more marked manifestations of stringency during his pontificate appear to have been prompted rather than spontaneous, his personal character inclining him to moderation and ease. Thus a monitory, issued in 1564, summoning the queen of Navarre before the Inquisition on a charge of Calvinism, was withdrawn by him in deference to the indignant protest of Charles IX.; and in the same year he published a bull granting the use of the cup to the laity of Austria and Bohemia. One of his strongest passions appears to have been that of building, which somewhat strained his resources in contributing to the adornment of Rome, and in carrying on the work of restoration, erection, and fortification in various parts of the ecclesiastical states. A conspiracy against him, headed by the Catholic fanatic Benedetto Accolti, was discovered and crushed in 1565. He died shortly afterwards, on December 9th of that year, and was succeeded by Pius V.

PIUS V. (Michele Ghislieri), pope from 1566 to 1572, was born at Bosco in the duchy of Milan, January 17, XIX. — 20

1504. At the age of fourteen he entered the Dominican order, passing from the monastery of Voghera to that of Vigevano, and thence to Bologna. Having been ordained priest at Genoa in 1528, he settled at Pavia, where he lectured for sixteen years. He soon gave evidence of the opinions which found a more practical expression in his pontificate, by advancing at Parma thirty propositions in support of the papal chair and against the heresies of the time. As president of more than one Dominican monastery he proved himself a rigid disciplinarian, and, in accordance with his own wish to discharge the office of inquisitor, received an appointment to that post at Como. His zeal provoking resentment, he was compelled in 1550 to return to Rome, where, after having been employed in several inquisitorial missions, he was elected to the commissariat of the Holy Office. Paul IV., who while still Cardinal Caraffa had shown him special favour, conferred upon him the bishopric of Sutri and Nepi, the cardinalate with the title of Alessandrino, and the honour—unique in one not of pontifical rank—of the supreme inquisitorship. Under Pius IV. he became bishop of Mondovi in Piedmont, but his opposition to that pontiff procured his dismissal from the palace and the abridgment of his authority as inquisitor.

Before Ghislieri could return to his episcopate, Pius IV. died, and on January 7, 1566, he was elected to the papal chair with duly attendant prodigies, his coronation taking place on his birthday, ten days later. Fully alive to the necessity of restoring discipline and morality at Rome to ensure success without, he at once proceeded to reduce the cost of the papal court, compel residence, regulate inns, expel prostitutes, and assert the importance of ceremonial. In his wider policy, which was characterized throughout by a stringency which tended to defeat its own ends, the maintenance and increase of the efficacy of the Inquisition and the enforcement of the canons and decrees of the Tridentine council had precedence over all other considerations. The prudence of Commendone alone saved him at the commencement of his pontificate from trouble with Germany, as in the general diet of the empire at Augsburg (March 26, 1566) Pius saw a threatened invasion of his own supremacy and was desirous of limiting its discussions. In France, where his influence was stronger, he directed the dismissal of Cardinal Odet de Coligny and seven bishops, nullified the royal edict tolerating the extra-mural services of the Reformers, introduced the Roman catechism, restored papal discipline, and strenuously opposed all compromise with the heretics—his exertions leading up in no small degree to the massacre of St Bartholomew. In the list of more important bulls issued by him the famous bull "In Coena Domini" (1568) takes a leading place; but amongst others throwing light on his character and policy there may be mentioned his prohibition of quæstuary (February 1567 and January 1570); the condemnation of Michael Baius, the heretical professor of Louvain (1567); the reform of the breviary (July 1568); the denunciation of the *dirum nefas* (August 1568); the banishment of the Jews from the ecclesiastical dominions except Rome and Ancona (1569); the injunction of the use of the reformed missal (July 1570); the confirmation of the privileges of the Society of Crusaders for the protection of the Inquisition (October 1570); the prohibition of discussions concerning the miraculous conception (November 1570); the suppression of the Fratres Humiliati for alleged profligacy (February 1571); the approbation of the new office of the Blessed Virgin (March 1571); the enforcement of the daily recitation of the canonical hours (September 1571); and the purchase of assistance against the Turks by offers of plenary pardon (March 1572). His antagonism to Elizabeth was shown, not only in the countenance lent by

him to Mary Stuart and those who sought in her name to deliver England "ex turpissima muliebris libidinis servitute," but in the publication of a bull, dated April 27, 1570, excommunicating Elizabeth and releasing her subjects from their allegiance. His energy was in no respect more favourably exhibited than in his persistent and successful endeavours to form a general league against the Turks, as the result of which the battle of Lepanto (Oct. 7, 1571) was won by the combined fleet under Colonna. Three national synods were held during his pontificate—at Naples under Cardinal Alfonso Caraffa (whose family had, after inquiry, been reinstated by Pius V.), at Milan under Carlo Borromeo, and at Mechlin. His death took place on May 1, 1572, and he was canonized by Clement XI. on May 24th 1712. He was succeeded by Gregory XIII.

PIUS VI. (Giovanni Angelo Braschi), pope from 1775 to 1799, was born at Cesena, December 27, 1717. After taking the degree of doctor of laws in 1735, he went to Ferrara and became the private secretary of Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753. His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV. who appointed him one of his secretaries and canon of St Peter's. In 1758 he was raised to the prelate and then to the treasurership of the apostolic chamber by Clement XIII., whose successor, Clement XIV. created him cardinal on the 26th April 1773. On the death of Clement XIV. and after protracted debate, Braschi was elected to the vacant see on the 15th February 1775. His assumption of the title Pius VI. even then recalled to the populace the verse current in the pontificate of Alexander VI. "Semper sub Sextis perdita Roma fuit," though his earlier acts gave fair promise of liberal rule and reform in the defective administration of the papal states. He showed discrimination in his benevolences, reprimanded Potenziani, the governor of Rome, for unsuppressed disorders, appointed a council of cardinals to remedy the state of the finances and relieve the pressure of imposts, called to account Nicolo Bischi for the expenditure of moneys intended for the purchase of grain, reduced the annual disbursements by the suppression of several pensions, and adopted a system of bounties for the encouragement of agriculture. The circumstances of his election, however, involved him in difficulties from the outset of his pontificate. He had received the support of the ministers of the crowns and the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief *Dominus ac Redemptor* (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the *zelanti*, who believed him secretly inclined towards Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. As the result of these complications, Pius was betrayed into a series of half measures which gave little satisfaction to either party. The case of Ricci and the other Jesuits imprisoned in the castle of St Angelo had scarcely been settled, by formal discountenance but informal relaxations and final release, before the question became an international one. Driven from devout Catholic countries, the members of the condemned society found an asylum under the rule of the heretic Frederick II. and the schismatic Catherine II., who welcomed them upon educational grounds. A long correspondence ensued in which both monarchs maintained their right, Catherine carrying the matter still further and wresting from Pius a series of important concessions. Even in countries acknowledging the papal authority practical protests arose which tended to its limitation. In Austria the social and ecclesiastical reforms undertaken by Joseph II. and his minister

Kaunitz touched the supremacy of Rome so nearly that in the hope of staying them Pius adopted the exceptional course of visiting Vienna in person. He left Rome on the 27th February 1782, and was magnificently received by the emperor, but his mission was unattended by any marked success. In Naples difficulties necessitating certain concessions in respect of feudal homage were raised by the minister Tannucci, and more serious disagreements arose with Leopold I. and Ricci, bishop of Pistoia and Prato, upon questions of reform in Tuscany. The outbreak of the French Revolution followed, and Pius in vain endeavoured to preserve the ecclesiastical discipline and property. The old Gallican Church was suppressed; the pontifical and ecclesiastical possessions in France were confiscated; and an effigy of himself was burnt by the populace at the Palais Royal. The murder of the Republican agent, Hugo Basseville, in the streets of Rome (January 1793) gave new ground of offence; the papal court was charged with complicity by the French Convention; and Pius threw in his lot with the league against France. In 1796 Napoleon invaded Italy, defeated the papal troops, and occupied Ancona and Loreto. Pius sued for peace, which was granted at Tolentino on the 19th February 1797; but on the 28th December of that year, in a riot created by some Italian and French revolutionists, General Duphot of the French embassy was killed and a new pretext furnished for invasion. General Berthier marched to Rome, entered it unopposed on February 10, 1798, and, proclaiming it a republic, demanded of the pope the renunciation of his temporal authority. Upon his refusal he was taken prisoner, and on February 20th was escorted from the Vatican to Siena, and thence from place to place—in succession to Florence, Parma, Piacenza, Turin, Grenoble, and Valence, where he died six weeks later, on the night of the 28th August 1799. Pius VII. succeeded him.

The name of Pius VI. is associated with many and often unpopular attempts to revive the splendour of Leo X. in the promotion of art and public works,—the words “*Munificentia Pii VI. P.M.*,” graven in all parts of the city, giving rise amongst his impoverished subjects to such satire as the insertion of a minute loaf in the hands of Pasquin with that inscription beneath it. He is best remembered in connexion with the establishment of the museum of the Vatican, commenced at his suggestion by his predecessor, and with the attempt to drain the Pontine Marshes. In the latter undertaking large sums were expended to such small purpose that the phrase “*Sono andate alle paludi Pontine*” passed into a proverb applied to funds employed in extravagant projects. The chief result was the restoration of the Appian Way by the removal of the additions of Trajan and Theodoric with later accumulations, and the erection of a new viaduct to Terracina upon the original road of Appius Claudius.

PIUS VII. (Gregorio Luigi Barnaba Chiaramonti), pope from 1800 to 1823, was born at Cesena on August 14, 1742. After studying at Ravenna, he entered the Benedictine monastery of St Mary in his native town, but was almost immediately sent by his superiors to Padua and to Rome for a further course of studies in theology. He then held various teaching appointments in the colleges of his order at Parma and at Rome. He was created an abbot of his order by Pius VI., who appointed him bishop of Tivoli on the 16th December 1782, and on February 14, 1785, raised him to the cardinalate and the see of Imola. At the death of Pius VI. the conclave met at Venice on the 1st December 1799, with the result that Chiaramonti was declared his successor on March 14, 1800, and crowned on the 21st of that month. In the following July he entered Rome, appointed Cardinal Consalvi secretary of state, and busied himself with administrative reforms. His attention was at once directed to the ecclesiastical anarchy of France, where, apart from the broad schism on the question of submission to the republican constitution, discipline had been so far neglected that a large pro-

portion of the churches were closed, dioceses existed without bishops or with more than one, Jansenism and marriage had crept into the ranks of the clergy, and indifference or hostility widely prevailed amongst the people. Encouraged by the intimation through Cardinal Martiniana of Napoleon's desire for the re-establishment of the Catholic religion in France, Pius appointed Caselli and Archbishop Spina to arrange a concordat with three nominees of Napoleon—Joseph Bonaparte, Cretet, and the Vendean priest Bernier. Difficulties having arisen, the aid of Consalvi was called in, and the concordat, signed at Paris on July 15th, was ratified by Pius on the 14th August 1801. Its value, however, from the pontifical point of view was considerably lessened by the “*Articles Organiques*” appended to it by the French Government on the 8th April 1802. In 1804 Napoleon opened negotiations to secure at the pope's hands his formal consecration as emperor. After some hesitation Pius was induced to perform the ceremony at Notre Dame and to extend his visit to Paris for four months. He returned to Rome on the 16th May 1805 with many expressions of good will; but in the October following the French troops, in evacuating the kingdom of Naples, suddenly occupied Ancona upon the alleged necessity of protecting the Holy See. Resistance by force was out of the question, but to a requisition from the emperor that all Sardinians, English, Russians, and Swedes should be expelled from the pontifical states, and that vessels of all nations at war with France should be excluded from his ports, Pius replied by asserting the independence and neutrality of his realm. After negotiations had dragged on for two years, in the course of which the French occupied the chief Adriatic ports, Civita Vecchia was seized and the papal troops placed under French officers. On the 2d February 1808 Rome itself was occupied by General Miollis; a month later the provinces of Ancona, Macerata, Fermo, and Urbino were united to the kingdom of Italy, and diplomatic relations between Napoleon and Rome were broken off; finally, by a decree issued from Vienna on May 17, 1809, the emperor declared the papal states reunited to France by resumption of the grant of Charlemagne. Pius retaliated by a bull, drawn up by Fontana and dated June 10, 1809, excommunicating the invaders; and, to prevent insurrection, Miollis—either on his own responsibility, as Napoleon afterwards asserted, or by order of the latter—employed General Radet to take possession of the pope's person. The palace on the Quirinal was broken open during the night of July 5th, and, on the persistent refusal of Pius to renounce his temporal authority, he was carried off, first to Grenoble, thence after an interval to Savona, and in June 1812 to Fontainebleau. There he was induced, on the 25th January 1813, to sign a new concordat, which was published as an imperial decree on the 13th February. On conference with the cardinals, however, Pius withdrew his concessions and proposed a concordat upon a new basis. At first no attention was paid to this, and, when after the French armies were driven from Germany Napoleon endeavoured to purchase a new concordat by offering to restore the papal possessions south of the Apennines, Pius refused to treat with him from any place other than Rome. The order for his departure thither reached him on the 22d January 1814, and after a brief delay at Cesena he entered Rome on the 24th May 1814. With his states restored to him by the congress of Vienna and freed from the Napoleonic terror, he devoted the remainder of his life to social and ecclesiastic reform in accordance with the modern spirit, suppressing many of the feudal survivals, abolishing torture, reconstituting civil and judicial procedure, and giving effect to many beneficial changes introduced by the French. His long and in many

respects admirable pontificate of more than twenty-three years' duration was brought to a close by an accident. His thigh having been broken by a fall in July 1823, acute inflammation supervened, and he died on the 20th August in that year. His successor was Leo XII.

PIUS VIII (Francesco Xaviero Castiglioni), pope, was born at Cingoli near Ancona on November 20, 1761. After having been appointed bishop of Montalto in 1800, cardinal and bishop of Cesena in 1816, and bishop of Frascati in 1821, he was in 1829 declared successor of Leo XII. His unimportant pontificate was of little more than sufficient duration to enable him to give expression to convictions largely characterized by narrowness and intolerance in his choice of Cardinal Albani as head of affairs, and in his encyclical letter against the liberty of the press, civil marriage, and similar impious institutions. His death took place at Rome on the 30th November 1830. He was succeeded by Gregory XVI.

PIUS IX. (Giovanni Maria Mastai Ferretti), pope from 1846 to 1878, was born 13th May 1792 at Sinigaglia, near Ancona, the fourth son of Count Jerome and the Countess Catherine Vollazi of the same place. The family of Mastai is of ancient descent, and its representatives have frequently filled the office of mayor in Sinigaglia. The title of count was first given to its head by Prince Farnese, duke of Parma, towards the close of the 17th century. Somewhat later the elder branch, having become allied by marriage with the last representative of the family of Ferretti, assumed its second name. From the age of eleven to sixteen Giovanni received his education at the college of Piarists at Volterra, in Tuscany; a liability to epileptic fits precluded, however, much application to study. On one occasion, when thus attacked, he fell into a lake and was only saved from drowning by the intervention of a herdsman who observed the occurrence. A handsome lad, with a certain charm of expression and demeanour which characterized him throughout his life, he frequently attracted the attention of visitors to the college. On leaving Volterra, he conceived an attachment for a lady (afterwards a duchess), and the non-recital of his passion is said to have been a main cause of his resolution to enter the church. In 1818 he was invited to accompany Monsignor Odescalchi, a prelate attached to the pontifical court, on a visitation tour in his native province. On returning to Rome, he was encouraged by Pius VII. to persevere in his design of entering the church, was admitted (18th December 1818) to deacon's orders, and celebrated his first mass at the church of S. Maria del Falgiani on Easter Sunday 1819. His benevolent disposition had led him about this time to interest himself in an orphanage, familiarly known by the name of "Tata Giovanni," and he was now appointed by Pius to preside over the establishment, and continued to fill the post for five years. In 1823 he accompanied the apostolic delegate, Monsignor Muzi, to the republic of Chili, and remained at Santiago for two years, actively engaged in missionary labours. In 1825 he returned to Rome, was made a canon of S. Maria in the Via Lata, and appointed to preside over the hospice of San Michele,—a vast charitable institution for destitute children. Here he remained somewhat less than two years, being promoted 21st May 1827, by Leo XII., to the archbishopric of Spoleto. His residence in that city was marked by many acts of benevolence, and especially by the foundation of a large orphanage where poor children were maintained and educated and also taught some mechanical art. Here, as at Rome, his genuine kindness and conciliatory disposition made him deservedly popular, but his defects were also not less apparent. He had allowed the hospice to become financially embarrassed, and after succeeding to the episcopal

office showed himself incapable of duly regulating his own expenditure.

During the insurrectionary movements which followed upon the election of Gregory XVI. to the papal chair, headed by Menotti and the two Napoleons—Charles Louis (afterwards emperor of the French) and his brother—Archbishop Mastai did his best to protect the insurgents. He disapproved of the reactionary policy of the new pope, and strongly resented the oppressive rule of the Austrians. When Napoleon (against whom sentence of death had been pronounced) fled to Spoleto, the archbishop, to whom he applied for help, obtained for him the services of an officer who conducted him beyond the frontier to a place of safety. In the following year (1832) he was translated to the bishopric of Imola, and a few years later was elected a cardinal, being reserved *in petto* in the consistory of 23d December 1839, and proclaimed cardinal 14th December 1840. It was not until overcome by the persuasion of others that Gregory XVI. consented to bestow this dignity on his future successor. He is said to have expressed his conviction that Mastai's liberal tendencies and impulsive disposition unfitted him for power, and that if he should ever become pope he would be the ruin of the church. During the tenure of his bishopric at Imola, Mastai gained additional reputation by the foundation of various philanthropic institutions and marked simplicity of life.

On the death of Gregory XVI., he repaired to Rome, and on the evening of 16th June 1846 was elected to the papal chair as Pius IX., having chosen this name out of respect for his predecessor in the see of Imola, Pius VII. His election, at the final scrutiny, proved to be unanimous, the cardinals Patrizzi and De Angelis throwing all their influence in his favour. On the following morning, when it was too late, the Austrian ambassador received instructions from his Government to veto the new pope's election.

Pius's first act in his new capacity was to proclaim a general amnesty for political offences, whereby thousands of unhappy beings who had dragged out weary years in prison or in exile, ignorant, many of them, even of the offences with which they were charged, were restored to society. With genuine catholicity of feeling he visited and relieved even the poor Jewish population in the city. He authorized the construction of railways, organized a civil guard, and considerably modified the restrictions on the press. In order to develop further reforms he instituted a commission largely composed of laymen; and in 1847 he brought forward his scheme of a *Consulta*, or council of state, designed to assist him in the general temporal government. But, notwithstanding these concessions, the supreme power remained in the hands of ecclesiastics, and no measure passed by the council could acquire validity until it had been examined and approved in a conclave of cardinals. Hence, although both MAZZINI (*q.v.*) and Garibaldi were among his avowed supporters, the liberal party were still far from satisfied. His policy was regarded, on the one hand, with extreme dissatisfaction by Austria, and on the 17th July 1847 that power sent a force of 1500 men into Ferrara, where she was entitled by the treaty of 1815 to maintain a garrison. To this direct menace Pius replied by counter demonstrations and an indignant protest, but hostilities were ultimately averted. His policy was viewed with not less dislike at the court of Naples, but by the rest of Italy and throughout Europe he was at this time regarded as the champion of the national rights of his countrymen. Such was the posture of affairs when the revolution in Paris (February 1848) fanned into flames the already smouldering elements of insurrection throughout Europe. The Austrians were driven out of Milan; a republic was proclaimed in Venice

(see ITALY, vol. xiii. pp. 488-89); and a "free Italy" became the general cry. At first Pius, who felt but little sympathy with the views represented by the son of Philippe Egalité, seemed disposed to head the movement. He dismissed his state-secretary, Gizzi, an irresolute and timorous politician, and appointed Cardinal Ferretti in his place. On 14th March 1848 appeared the *Statuto Fondamentale*, a more complete scheme for the reorganization of the temporal government of the papal states. By this two deliberative assemblies were created,—the first, the high council, the members of which were to be nominated by the pope himself for life; the second, the council of deputies, to be elected by the people, and to be entrusted with the chief voice in all questions relating to taxation. Over both these bodies, however, the college of cardinals retained the supreme authority; without its consent no measure could acquire legal validity. Liberty of the press was promised, but the ecclesiastical censorship was to be retained. A new ministry was formed, which, with two exceptions (Antonelli and Morichini), was composed of laymen. But at this juncture Pius began to waver. Although he had hitherto shown no sympathy with the Jesuits, he endeavoured to protect them against the measures now brought forward with a view to their expulsion, and when his general, Durando, crossed the Po without his orders, and denounced the Austrians as "the enemies of the cross of Christ," he disowned, in an allocution (29th April), all intention of participating in an offensive war for the purpose of rectifying the boundaries of Italy, and at the same time disavowed all complicity in the schemes then in agitation for creating an Italian federal republic, with himself as the nominal head. This apparent desertion of the national cause, at a time when the public mind had been roused to the highest pitch of excitement by the course of events at other centres, created an irreparable breach between Pius and the people. His new chief minister, Mamiani, who wished to see him a constitutional monarch, advocated further concessions—the handing over of the political government to the new assemblies and a responsible ministry. But after the Austrian successes in the north and Radetsky's entry into Milan (5th August), Mamiani was dismissed, and his place was filled by Count Rossi, the French ambassador, a statesman of signal ability and intrepid character, but of conservative views. On the 15th November 1848, as Rossi was alighting at the steps of the house of assembly, he was assassinated in broad daylight. It was an ominous symptom of the prevailing temper of the capital that this atrocious act elicited no expression of disapproval in the assembly, and drew forth no marks of sympathy with the victim's family. Two days later a numerous mob, largely composed of disbanded soldiers, assembled in the square of the Quirinal, and proffered fresh demands, at the same time intimating their intention, if these were not conceded, of commencing a general massacre of the inmates, excepting only the pope himself. After his secretary, Palma, had been shot by a bullet, Pius, in order to avert further bloodshed, made the requisite concessions, and assented to the formation of a new ministry, while he himself was made a virtual prisoner. On the 24th November he effected his escape, with the connivance of the French Government, to Gaeta, disguised as a dependant of Count Spaur, the Bavarian minister. Thus terminated what has been described as "the first and only attempt of a pope to govern in a liberal spirit."

From Gaeta he published a formal protest against the violence to which he had been subjected, and whereby his latest enactments had been extorted from him, at the same time declaring all measures decreed in Rome during his absence null and void. Gioberti, the Sardinian

minister, endeavoured without success to gain his concurrence in a new scheme for the formation of an Italian federation of princes. In the following February it was resolved in a consistory of cardinals to appeal to the chief Catholic powers (France, Austria, Spain, and Naples) for their aid in bringing about the re-establishment of the temporal sovereignty. About the same time (3d February 1849), as if to mark his undisturbed sense of his spiritual supremacy, Pius himself addressed an encyclic to the superior Catholic clergy throughout the world, enjoining that on appointed days of the year the doctrine of the Immaculate Conception B.V.M. should be preached throughout their dioceses. The decisive defeat of the Sardinian forces at Novara by Radetsky (23d March 1849) encouraged the papal party now to demand that Pius should be reinstated at Rome without any conditions being attached to his restoration. This demand created a divergence of opinion among the above-named powers; eventually General Oudinot landed at Civita Vecchia with 10,000 French soldiers, and De Tocqueville, the French minister for foreign affairs, sought to induce Pius to resume his sovereignty on the basis of the *Statuto Fondamentale*. This he resolutely refused to do, and after the occupation of Rome by Oudinot's forces he was permitted to return (12th April 1850) unfettered by any condition whatever.

Pius returned an altered man in relation to his state policy, in which, in fact, he was from this time guided almost entirely by Antonelli. A certain profession of a design to reform abuses was indeed made, but the former ecclesiastical ascendancy in the government was re-established, while the pope entered into the closest relations with the Jesuit party. Notwithstanding his specious disclaimers of any desire to take revenge for the past, the *Documenti Officiali*, published in 1860, prove that little mercy was shown to those who were suspected of disaffection. As, however, the continuance of the French occupation relieved him from any anxiety with respect to the maintenance of order, Pius was enabled to devote his attention chiefly to the objects which undoubtedly lay nearest to his heart,—the more complete definition of Roman dogma and the enhancement of the prerogatives of his office. In this direction his views had never been characterized by any liberality, as is sufficiently shown by his encyclic of 9th November 1846, his letter to the archbishop of Cologne (3d July 1847), and his allocution of 17th December 1847, in which all the modern tendencies to a more philosophic interpretation of doctrine are visited with unqualified condemnation. He now proceeded skilfully to avail himself of the reaction that began to set in, especially in Germany and in England, after the repression of the revolutionary movements, by taking, as the burden of his allocutions, the essential connexion between political innovation and freedom of scientific or religious thought. The activity of the Jesuits was studiously encouraged; the "beatification" of several eminent deceased members of their order was proclaimed; and lives of the saints, full of marvellous and legendary incidents, were widely circulated among the poorer laity. A combination of circumstances, at this period, largely contributed to the success of these efforts both in Europe and in America. By the bull "Ineffabilis Deus" (8th December 1854) the doctrine of the immaculate conception was formally "defined," as a dogma binding on the acceptance of all the faithful, and in pamphlets favourable to the assumptions of the curia it was pointed out that the supreme pontiff had thus defined the doctrine *without recourse to any council*. In 1862 the canonization of six hundred and twenty missionaries, who had met with martyrdom in Japan some two centuries and a half before, was made the occasion of an imposing ceremonial. In a letter (11th December 1862) to

the archbishop of Munich, the teaching of Frohschammer, a distinguished professor of philosophy in the university in that city, was singled out for severe reprobation. The famous encyclic *Quanta cura*, and the *Syllabus*, or list of prevalent errors calling for especial reprobation, appeared in December 1864.

The war between France and Austria and the treaty of Villafranca (8th July 1859; see ITALY, vol. xiii. p. 490) seemed at one time likely to result in placing the temporal power on a basis somewhat resembling that indicated in Gioberti's pamphlet of 1843, and the ultramontane party waited with lively expectation the assembling of the congress. Among the inhabitants of the Romagna themselves, however, discontent with the political administration was intense. The papal rule had become almost as oppressive as that at Naples; and the prisons of Rome were filled with inmates against whom no more definite charge could be brought than that of suspected disaffection towards the Government. The manner in which the currency had been tampered with was alone sufficient to produce the gravest discontent, and the *lira papalina* was eventually accepted at the money-changers' only at a heavy loss to the holder. When, in the spring of 1857, Pius visited central Italy, it was observed that, while in other provinces he was greeted with enthusiasm as the pope, in his own dominions he was received with sullen coldness. A pamphlet published at Paris in December 1859 (ascribed to imperial inspiration), after describing the condition of the Romagna, openly raised the question of the continuance of the temporal power, and suggested that it would at least be desirable that it should be restricted to the capital itself. Pius replied in an encyclic issued on the 19th of the ensuing January—a document since widely known as his *Non Possumus*. His obstinacy proved of no avail. The Romagna was occupied by Sardinia, and the Central-Italian states shortly afterwards formed themselves into a league to prevent its reoccupation by the pontifical forces. Antonelli rejoined by raising a motley force, composed of French, Belgians, Bavarians, and Irish, who were placed under the command of Lamoricière, an able French officer who had seen active service in Algiers. There can be no doubt that, in making this apparently hopeless effort, the curia was deluded by the belief that, if matters proceeded to extremities, France would intervene in its behalf. After a stubborn resistance at Ancona, the superior forces of Sardinia prevailed, and in September 1860 the whole of the States of the Church, with the exception of the *patrimonium Petri* (see POPedom), were annexed to the kingdom of Victor Emmanuel.

From the reduction of Ancona to the year 1870 Pius was maintained in Rome only by a French garrison. The emperor of the French was reluctant to appear altogether to desert the papal cause, while Cavour was unwilling, in like manner, to proceed to extremities. After the capture of Garibaldi at Aspromonte, however, Victor Emmanuel felt himself strong enough to put in a formal claim for Rome; and it was eventually arranged, by the convention of 15th September 1864, that the French should withdraw from the city before the end of 1866. This stipulation was duly observed, and on the 11th December 1866 the last of the French forces quitted the capital. The engagement was, however, virtually violated by the entry, in the following year, of the Antibes legion, and for some time longer the French soldiery continued to ward off both the daring assaults of Garibaldi and the more insidious approaches of Ratazzi. In this manner, at the outbreak of the war of 1870, France had come again to be looked upon as the ally of the papacy; and the overweening claims put forward by Pius in convening a general council to proclaim the dogma of Papal Infallibility were generally

interpreted as in a certain sense correlative with the aggressive designs of France on Protestant Germany. The dogma was decreed in the Vatican on the 18th July, but not without strenuous opposition on the part of some of the most distinguished members of the Catholic episcopal order, who, at the same time, were staunch supporters of the temporal power (see OLD CATHOLICS). At nearly the same time the occupation by the French came definitively to an end. Their forces were withdrawn from Civita Vecchia at the outbreak of the war, when the Duc de Gramont announced that his Government relied on the convention of 1864, whereby Italy was bound not to attack the papal territory. That territory being now, however, again exposed to the dangers of revolution, Victor Emmanuel, on receiving the tidings of the battle of Gravelotte, notified to Pius that "the responsibility of maintaining order in the peninsula and the security of the Holy See" had devolved upon himself, and that his army must enter the pontifical dominions. This intimation was received by Pius with demonstrations of the liveliest indignation, but the appearance of the Sardinian troops was hailed by his own subjects with enthusiasm. On arriving outside Rome, General Cadorna summoned the garrison to surrender, and after a short bombardment the white flag was hoisted. On the following day (21st September 1870) the Zouaves, some nine thousand in number, after receiving, as they stood massed in the square of St Peter's, the pontifical blessing, marched out of Rome, and the temporal power of the pope had ceased to exist.

For the rest of his days Pius IX. remained unmolested at the Vatican, while the king resided at the Quirinal. The pontiff was virtually a prisoner; and his position, although viewed with comparative indifference in Rome, was regarded with not a little sympathy by the Catholic world at large. The tribute of Peter's Pence was revived in order to supply, in some measure, the loss of his alienated revenues; and numerous pilgrimages, in which distinguished and wealthy individuals took part, were made to St Peter's from all parts of Catholic Christendom, and especially from England. His advanced years, fine presence, dignified demeanour, and elasticity of spirits (unbroken by his adverse fortunes) combined to invest both the person and the office of the pope with a kind of fascination for devout minds, which those about him well understood how to turn to the best advantage. Occasionally, however, his naturally impetuous temper still manifested itself. The complicity of the Roman Catholic clergy with the Polish insurrection of 1863 had been punished by Russia with excessive rigour, and, on receiving the Russian deputies who came to offer the customary felicitations on New Year's Day 1866, Pius so far forgot the proprieties of the occasion as to himself address them in terms of reproach. A suspension of diplomatic relations ensued; and Russia now eagerly availed herself of the pretext afforded by the promulgation of the new dogmas to aim a severe blow at Roman Catholic influence within her dominions, by annexing to the Russian Church the bishopric of Chelm, with a population of over 300,000 souls. Pius showed his resentment by espousing the side of Turkey in the struggle of that country with the Russian power. On the 3d June 1877 he celebrated the fiftieth anniversary of his consecration to the archbishopric of Spoleto, and the event was made singularly memorable by the spectacle of numerous deputations, bearing costly offerings, from all parts of the world. Pius died on the 8th of the following February, and was succeeded by Cardinal Pecchi as Leo XIII.

The life of Pius has been written by the late J. F. Maguire (2d ed., 1878), and by Leopold Wappmannsperger, *Leben und Wirken des Papstes Pius des Neunten* (Ratisbon, 1878). Both

authors write from the ultramontane point of view, but the latter much more in detail, giving original documents and information respecting events subsequent to 1870 not to be found in English sources. Nippold's *Handbuch der neuesten Kirchengeschichte*, vol. ii., supplies an outline of the papal policy in connexion with other contemporaneous religious movements; and a concise but more impartial sketch will be found in Ranke, *Die römischen Päpste* (7th ed.), ii. 162–208. The literature connected with the Vatican Council is given under OLD CATHOLICS. (J. B. M.)

PIZARRO, FRANCISCO (c. 1471–1541), discoverer of Peru, and the principal hero of its conquest, born at Truxillo in Estremadura, Spain, about the year 1471, was an illegitimate son of Gonzalo Pizarro, who as colonel of infantry afterwards served in Italy under Gonsalvo de Cordova, and in Navarre, with some distinction. Of Pizarro's early years hardly anything is known; but he appears to have been only poorly cared for, and his education was certainly neglected. Shortly after the news of the discovery of the New World had reached Spain he was in Seville, and thence found his way across the Atlantic; there he is first heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá under Alonso de Ojeda, by whom, in his absence, he was entrusted with the charge of the unfortunate settlement at San Sebastian. Afterwards he accompanied Balboa to Darien; and under Balboa's successor, Pedrarias, he received a "repartimento," and became a cattle farmer at Panama, where in 1522 he entered into a partnership with a priest named Hernando de Luque and a soldier named Diego de Almagro for purposes of exploration and conquest towards the south. An expedition along the coast of New Granada (November 1524) was unfortunate, but supplied various confirmations of rumours previously heard as to the existence of a great and opulent empire farther to the south. On March 10, 1526, Pizarro, Almagro, and Luque renewed their compact, but in a much more solemn and explicit manner, to conquer and divide equally among themselves this empire still undiscovered, and Pizarro and Almagro, with a force of about one hundred and sixty men, again sailed from Panama. The force was too small to effect much at the time, and was at length recalled by the governor, but Pizarro was not to be shaken, and, though he was left for months with but thirteen followers on a small island without ship or stores, persisted in his enterprise till at length he had coasted as far as to about 9° S. lat., and obtained distinct accounts of the Peruvian empire. The governor still showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panama for Spain in the spring of 1528, reaching Seville in early summer. After long and tedious delays, the queen, in Charles's absence, executed at Toledo on 26th July 1529 the famous *capitulacion* by which Pizarro was upon certain conditions made governor and captain-general of the province of "New Castile" for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy. One of the conditions of the grant was that within six months he should raise a sufficiently equipped force of two hundred and fifty men, of whom one hundred might be drawn from the colonies; but this he had some difficulty in fulfilling. Sailing from San Lucar clandestinely (for his due complement was not yet made up) in January 1530, Pizarro was afterwards joined by his brother Hernando with the remaining vessels, and when the expedition left Panama in January of the following year it numbered three ships, one hundred and eighty men, and twenty-seven horses. A footing was established on the mainland at Tumbez, whence Pizarro set out for the interior in May 1532. San Miguel de Piura was founded a few weeks afterwards, and Caxamarca entered on November 15th. The subsequent movements

of Pizarro belong to the history of PERU (see vol. xviii. p. 677; and, for authorities, comp. p. 679).

PLAGUE (*λοῦός*, *Pestis*, *Pestilentia*). This name has been given to any epidemic disease causing a great mortality, and in this sense was used by Galen and the ancient medical writers, but is now confined to a special disease, otherwise called Oriental, Levantine, or Bubonic Plague, which may be shortly defined as a specific febrile disease, transmissible from the sick to healthy persons, accompanied usually by buboes and sometimes by carbuncles. This definition excludes many of the celebrated pestilences recorded in history,—such as the plague of Athens, described by Thucydides; that not less celebrated one which occurred in the reign of Marcus Aurelius and spread over nearly the whole of the Roman world (164–180 A.D.),¹ which is referred to, though not fully described, by the contemporary pen of Galen; and that of the 3d century (about 253), the symptoms of which are known from the allusions of St Cyprian (*Sermo de Mortalitate*). There is a certain resemblance between all these, but they were very different from Oriental plague.

Symptoms.—There are two chief forms:—(1) mild plague, *pestis minor*, larval plague (Radcliffe), *peste fruste*, in which the special symptoms are accompanied by little fever or general disturbance; and (2) ordinary epidemic or severe plague, *pestis major*, in which the general disturbance is very severe. Cases which are rapidly fatal from the general disturbance without marked local symptoms have been distinguished as fulminant plague (*pestis siderans*, *peste foudroyante*).

1. In the minor form of the disease spontaneous swellings of the glands occur, chiefly in groins and armpits, but also in neck or other parts, which either undergo resolution or suppurate. There is a certain amount of fever; the temperature is rarely high, but has been known to be 104° Fahr. The duration of the disease is ten to twenty days usually, but may be eight weeks, for most of which time the general health is little impaired and the patient able to go about as usual. It rarely, if ever, causes death, the only fatal case at Astrakhan in 1877 having been so through a complication. The disease is not obviously contagious; whether it is propagated by infection or not is unknown. It is possibly rather of a miasmatic character. This form of disease has sometimes preceded or followed severe epidemics, as in Mesopotamia (Iraq) on several occasions, 1873–78, and in Astrakhan, 1877; its importance in relation to the origin of plague has only lately been appreciated.²

It might be expected that gradations would be found connecting this form with the severe epidemic form; but this appears to be not usually the case, the latter form appearing somewhat suddenly and abruptly. Hence the minor form has probably often been regarded as a distinct disease, even when observed in plague countries.

2. As regards *pestis major*, or severe plague, the symptoms appear to have been nearly the same in all great epidemics for several centuries, if not for two thousand years, but will be best given from modern observations, such as those of Surgeon-Major Colvill, Dr Cabiadis, and others in Iraq, and recent observers in India. The early symptoms are sometimes like those of ague (shivers, often long continued, and pains in the limbs), but combined with nervous symptoms. The patient becomes distracted, tosses about in constant fear of something he cannot describe,

¹ Amm. Marcell., xxiii. 7; see Hecker, *De Peste Antoniana*, Berlin, 1835.

² Payne, *Trans. Epidem. Soc. of Lond.*, iv. 362; Tholozan, *La Peste en Turquie*, Paris, 1880; J. N. Radcliffe, *Report of Local Government Board*, 1879–80 (Supplement, pp. 24, 49), and article "Plague," in Quain's *Dictionary of Medicine*, London, 1882.

has a difficulty in understanding the questions put to him, and is slow in answering. He is often described as staggering like a drunken man. There is severe headache, intense thirst, and severe pain in the epigastrium. The eyes are red and turbid; the tongue swollen, dry, and fissured, sometimes black, sometimes remarkably white (Colvill). This condition may pass into coma even before fever sets in. In other cases bilious vomiting is the earliest symptom. The fever which sets in may last twenty-four to thirty hours, or more. The temperature may be 100° to 107° Fahr., or even higher; but in the most rapidly fatal cases there may be little or no fever. Generally there is obstinate constipation, but sometimes diarrhoea. Besides these symptoms there are certain special ones especially characteristic of plague.

(a) Buboes or glandular swellings are observed in all except very rapidly fatal cases. They occur in 45 or 50 per cent. of the cases in the groin, in 35 per cent. in the axilla, also less frequently in the neck or other parts. These swellings may occur before the fever, simultaneously with it, or some hours after it has set in. A sudden pain like that of a stab is felt in some region of the body, which has given rise to the superstition that the unfortunate victim was wounded by the arrow of an invisible demon,—a belief recorded in Constantinople in the 6th century, and said still to survive in Mohammedan countries. The buboes may suppurate, and free discharge of matter from them has in all times been held to be a favourable sign and conducive to recovery.

(b) Carbuncles were observed in about 2½ or 3 per cent. of the cases in recent epidemics in Irak. They are always an unfavourable sign.

(c) Petechiæ or hæmorrhagic spots on the skin have always been regarded as signs of the worst omen. Under the name of "tokens" they were considered in the English epidemics of the 16th century as the infallible signs of approaching death. "They appear generally only a few hours before death" (Colvill). Hodges (1665) noticed hardness which showed the existence of hæmorrhage under the skin. The skin is sometimes so covered with petechiæ as to become of a dark livid hue after death, recalling the name Black Death (Cabiadis).

The occurrence of the above symptoms, especially the first, in an idiopathic fever attacking many persons at one time is sufficient to make the diagnosis of plague.

A very notable and fatal form of the disease is that in which hæmorrhages from the lungs, stomach, bowels, nose, &c., occur. These are of the worst omen, and are seen in some cases where there are no buboes, and which are rapidly fatal. This was observed in Irak in recent epidemics, in the outbreak on the Volga in 1878-79, and in the plague of India. It was a noticeable symptom in the black death, and was observed even in the plague of the 6th century. The bleeding is mostly from the lungs, and is sometimes associated with other symptoms of lung affection. This form of the disease appears, however, to have no distinct historical or geographical limit. A similar hæmorrhagic form has been observed in small-pox and scarlet fever, and is always extremely fatal.

In all plague epidemics cases occur in which death takes place very rapidly, even within twenty-four hours, without the development of the special symptoms of the disease. Such cases are reported by Diemerbroek, Hodges, and others in the 17th century, and have been observed in recent epidemics in Irak, as well as in the recent plague on the Volga. Some are more like cases of poisoning than of infection, and much resemble the instances of death from the exhalations of dead bodies (cadaveric poisoning) which are met with from time to time. It is these which have given rise to the expression fulminant plague.

Duration.—The duration of an attack of plague may be from some hours to a month. Three-fifths of the cases observed by Mr Colvill were fatal on the third day, and the majority of cases in India had the same termination (Francis). Five-sixths of fatal cases end by the fifth day. Most of those who survive the fifth day get well; after the seventh day a patient in Baghdad was considered by his friends safe; and in Mr Colvill's cases only 4 per cent. of fatal cases died after the tenth day. In non-fatal cases with suppurating buboes the disease may be protracted to two or three weeks or a month.

Mortality.—Plague is the most fatal of all known diseases which affect large numbers of people. The mortality, according to official registers in Baghdad, was 55·7 per cent. of those attacked. Dr Cabiadis thinks this too high, owing to many cases of recovery not being reported. But in some epidemics the proportion of fatal cases is much higher. In Vetlanka it was about 90 per cent., and in some other villages on the Volga every person who took the disease died. The older accounts do not give the proportion of deaths and attacks.

Morbid Anatomy.—Examinations after death have not done much to elucidate the nature of plague, except negatively. The appearances are those of death from an acute infective disease, and resemble those of typhus, except for the special affection of the lymphatic glands. The brain and the lungs are found to contain excess of blood; the right side of the heart distended, the blood dark-coloured and undergoing rapid decomposition.¹ The spleen is found enlarged, and in a less degree the liver. The stomach and intestinal canal often show signs of inflammation and hæmorrhage, sometimes ulceration. The characteristic swelling of the lymphatic glands, both external and internal, is often accompanied by inflammation of the cellular tissue around. Petechial patches are sometimes found on the internal organs.²

Pathology of Plague.—All that is known of plague goes to show that it is a specific febrile disease depending on the reception into the body of a specific organic contagion, which becomes multiplied in the body of the patient. Analogy makes it very probable that this contagion is a living organism of the class *Bacteria*, but the suspected organism has not yet been discovered. The nearest ally of plague is typhus fever, so that some authorities have spoken of it as the typhus of hot climates, modified by temperature, &c., but this opinion does not appear to have ever been held by any competent physician who has examined the disease at first hand. It appears to be as distinct from typhus as this is from enteric fever, or other so-called typhoid diseases. It has also been thought that plague is related to intermittent or remittent malarious fevers; but the most recent observations show that there is no real connexion between these diseases. In India, says Dr Francis, neither intermission nor remission has ever been observed in plague. It is quite distinct from and in no way modified by the types of fever that are caused by malaria. Dr Cabiadis speaks to the same effect of plague in Irak, and insists that the physical conditions which favour the production of marsh poison are not necessarily favourable to plague.

External Conditions of Plague.—The nature of the soil

¹ This post-mortem decomposition of the blood is doubtless the cause of some appearances described with great particularity in the older accounts.

² Our knowledge of the morbid anatomy of plague is derived almost entirely from the observation of the French physicians in Egypt during the epidemic in 1835-36. Earlier observations are of no value, and in later epidemics of Irak and Russia none have been made. In India Drs Pearson and Francis made a few autopsies. Clot-Bey, *De la Peste en Égypte*, Paris, 1840; Bulard, *De la Peste Orientale*, Paris, 1839; Francis, *Indian Annals of Medical Science*, vol. i., 1854.

has little influence on plague. It may flourish in alluvial deltas, on calcareous ridges or granitic mountains. Moisture in the soil has generally been thought to be an important factor in its production, but, though often found in marsh situations, such as the banks of the Nile, the Euphrates, or even the Volga, it also occurs in India at elevations approaching 7000 feet, and in Kurdistan at 5000 to 6000 feet above the sea.

The temperature most favourable to plague is a moderately high one. The disease is unknown in the tropics. When prevalent in Egypt it was said never to penetrate farther south than Assouan. It has not crossed the plains of India within historic times. Where the disease does occur, a temperature of 80° to 85° or more, combined with absence of moisture, usually stops the epidemic. In Egypt it was observed to cease as an epidemic almost suddenly about the 22d to 24th of June, and not to begin again till September. In Irak it dies out suddenly during the summer. When the temperature rises above 86° it begins to diminish; and it ceases abruptly at a temperature of 113°. In India it has been observed by Dr Francis when the temperature of his tent was 83° to 95°, or in a grass hut to 105°, while the air was moist; but he thinks a lower temperature with dryness renders the poison inert.

On the other hand, in northern countries, the disease is usually checked by the cold of winter, starts up in the spring, and is most active in August and September. To this rule there have been some remarkable exceptions, such as the epidemic on the Volga in 1878-79, which raged during severe winter weather, and the great plague of Moscow in 1770.

Sanitary Conditions.—Of all the co-operating causes of the plague, *uncleanliness* is the most powerful,—meaning by this the accumulation of decaying animal matter around human bodies or dwellings. The saturation of the soil with filth is perhaps the most important point. A plague seat in Mesopotamia is thus described by Colvill:—"The ground is so saturated with moisture that the refuse of the village is neither absorbed nor evaporated, but . . . acquires the form of a bluish-black oily fluid, which surrounds the huts and covers the paths, and stains the walls 2 feet from the ground; and in fact the village is in such a state of filth that it requires to be seen to be believed." Of the people among whom the Pali plague of India raged it is said "they were filthy beyond conception" (Francis). There can be little doubt that European cities in the Middle Ages, and down to the 17th century, presented very similar conditions. These conditions may be considered to act by supplying a suitable environment for the life and growth of the organized poison (or bacterium) outside the human body. Where these are wanting one of the main factors in the spread and permanence of the disease will be absent, a fact which makes it probable that increased cleanliness is the chief cause of the disappearance of plague from Europe.

Overcrowded dwellings, especially with deficient ventilation, greatly favour the spread of the disease; but this is not necessarily correlative with density of population, and plague may flourish in thinly-peopled countries.

Of social conditions *poverty* has by far the most powerful influence on the spread and development of plague. Many plague epidemics have followed on years of famine, or been connected with destruction of crops and cattle. The races among which the disease is endemic are almost without exception under-nourished, if not destitute. In the villages on the Volga there appeared to the writer, in 1879, to be little destitution, though the diet of the people was very meagre. In all city epidemics the poor are the chief or almost the only sufferers. This is as true of Baghdad in the 19th century as it was of London in the

17th. Those of the upper classes who have been attacked have been chiefly doctors, clergy, officials, and others whose occupations take them among the sick.

Origin and Spread of Plague.—Although the above-mentioned conditions are those in which plague originates, and may be considered in a general way essential to its continued existence, it is plain that they do not account for its origin. Poverty, overcrowding, filth, and marsh soil, with a temperature suited to plague, occur in many parts of the world where this disease has never been heard of or has ceased to exist. The geographical distribution of diseases cannot, any more than the distribution of plants or animals, be explained by climatic causes alone. With regard to plague it is quite clear that there are some parts of the world where it is at home, or, as the phrase is, "endemic." In other parts it is probable (or, as some think, certain) that its existence, and even its periodical recurrence, depend on importation from an endemic centre. Although it is not always easy to distinguish between these cases, they must be considered separately.

In the case of an endemic disease we suppose that the poison is either kept in existence by continued transmission from one case to another, or that it can subsist outside the human body in soil, water, or otherwise. The first mode of existence is that of a pure contagious disease, such as small-pox; and it is plain that this mode of continued existence obtains in the case of plague also. It is not, however, clear that the second may not also be one of the modes of existence of plague, which would then be a so-called "miasmatic" disease like ague, as well as a contagious one. In India, for instance, the disease appears as if it depended on a poison in the soil, since it returns years after to the same spot, appearing in many villages simultaneously; and some morbid influence causes the death of animals (rats) which live under ground. Similar facts have been observed in China; and, if further inquiry should confirm the hypothesis, it would show that plague is (like anthrax or the "steppe murrain" of cattle) both miasmatic and contagious. If so, there is no difficulty in supposing the disease to be carried by contagion to a distant part, and there to be established in the soil, for a longer or shorter period, as the conditions are more or less favourable. The adoption of this hypothesis would remove many of the difficulties attending the explanation of plague epidemics, and to some extent reconcile the controversies of the last three centuries between the "contagionist" and "non-contagionist" schools. It has been maintained by the former that European epidemics have always been caused by the importation of the disease from its home in the East, by the latter that it arose on European soil in the same way as in Egypt or Syria.

In the case of an imported non-endemic disease, the only question which arises is how the importation is effected,—whether the disease may be brought by the air alone, whether by infected persons only, or whether also by objects which have been in close relation to infected persons. Transmission of the disease by the air cannot be pronounced impossible; and there are facts to show that it is even probable with distances measured by yards, or possibly even hundreds of yards; but there is no evidence whatever that the disease has ever been carried by the air over distances measured by miles. Transmission of the disease by infected persons over longer or shorter distances, and from one country to another, is an established fact. Transmission by infected objects over great distances and from one country to another seems less clearly established. The last two cases must be separately considered.

1. It is clear that the first necessary condition to such transmission is *contagion*, or transference of the disease from the sick to the healthy. The existence of contagion

is shown by such facts as these:—when a case of plague breaks out in a house the other inmates are extremely likely to take the disease; and even in severe forms the plague does not cease till it has affected all or nearly all the household. This is indisputably an almost universal law. In the plague of London in 1603 it was said the disease entered hardly any house but it seized all that lived in it. And in 1879, on the Volga, in one village, as was ascertained by Mr Colvill and the present writer, the plague attacked five houses containing thirty-three persons, all of whom except two took the disease and died. In this respect plague resembles typhus. In the next place the disease will spread from an infected house to persons who have close relations with it. Thus in the villages on the Volga it was noticed that after one family was affected cousins and relations by marriage were the next to be attacked. Doctors and those visiting the house are also exposed to the risk, though in a less degree. In Vetlanka on the Volga three physicians and six surgical assistants died. On the other hand, doctors in some instances have singularly escaped from being attacked by the disease. In Egypt, in 1835, out of ten French physicians engaged one only died, nor was this immunity secured by any precautions. These experiences do not prove that the disease is not contagious, but they modify the exaggerated notions which have been held on the subject. The facts appear to be expressed by saying that it may undoubtedly be communicated from one person to another, but chiefly by breathing the air of the sick room, and this generally from prolonged not from momentary exposure,—so that the possibility of communication by chance meetings and similar contingencies may be disregarded. This view is that of Dr Cabiadis and others who have studied plague in Irak where no doctor or assistant, with one exception, suffered from the disease. It is not inconsistent with the experience recorded in Egypt. But it is clear that the intensity of contagion varies greatly in different epidemics. Modern experience contradicts the belief formerly entertained that contact with plague patients was the only or even the chief means of acquiring the disease. Everything tends to show that the atmosphere immediately surrounding the patient is the most effectual conveyer of contagion, and more effectual in proportion as the poison is concentrated. Precisely the same relations are observed with regard to typhus.

It has been disputed whether dead bodies convey infection of plague. Formerly the contagion from this source was greatly dreaded, and the task of burying thought to be specially dangerous. But the French in Egypt made more than a hundred post-mortem examinations without precautions and without harm. In Mesopotamia and in Russia no autopsies were made, but in the latter country some striking instances were noted of those engaged in burying the dead themselves dying of the plague. On the whole both facts and analogy lead to the belief that the disease may be derived from touching or being near a dead body, but not that there is any special danger of infection from this source.

2. It is a very momentous question whether the contagion is capable of being conveyed by clothes and other objects which have been in contact with the sick. The very general belief that this is so has been controverted only by the French physicians in Egypt, one of whom, Bulard, himself wore a shirt, taken direct from the body of a plague patient, for two days. They also state that in Egypt it was customary, when a plague epidemic was over, to sell the clothes and effects of those who had died of plague, without, as is affirmed, communicating the disease. In Constantinople they were customarily sold at once; and it is alleged that the dealers in old clothes did

not specially suffer. In 1835 the hospital at Cairo, where 3000 plague patients had been treated, was used, without even changing the bed coverings, immediately after the epidemic for other patients, without harm. Negative instances of this kind might be multiplied, but their importance is diminished by the consideration that the communicability of plague, by whatever means, is always found to become spontaneously weak at the decline of the epidemic, till it is extinct altogether. While the epidemic influence lasts there is abundant evidence that infected clothes, &c., are among the means by which the disease spreads. In Egypt, in 1835, two criminals condemned to death were for the sake of experiment placed in the clothes and beds of those who had died of plague, and both took the disease, one dying. Instances are given by White (*Treatise on the Plague*, p. 161, London, 1847) of the disease spreading "like wildfire" through the distribution of infected garments, and of those engaged in disinfecting clothes and other objects being suddenly seized with the complaint, e.g., on opening a box containing infected garments. While the reality of this mode of communication cannot reasonably be doubted, it admits of some question whether the plague has ever been thus conveyed over great distances, or from one country to another. The best known instance in England is the alleged transmission of plague from London to the village of Eyam in Derbyshire in 1665 by an infected parcel of clothes,—a story which cannot be criticized at this distance of time, but which presents some weak points.¹ Dr Cabiadis states that he has seen plague thus conveyed in Irak to places outside the existing focus of infection, but gives no details. On the whole we must consider the exportation of plague by clothes over great distances, and into countries not subject to the same epidemic conditions as the infected country, "not proven."

The communication of plague by merchandise or objects not personal, coming from an infected country, rests upon still more defective evidence, though at one time generally believed. In virtue of this belief all goods, especially those regarded as susceptible (as wool, furs, raw cotton, &c.), were, when coming from an infected or suspected country, subjected to disinfection under special regulations. But there is really no evidence that plague was ever thus transmitted or that these regulations kept it out. On the contrary there are numberless instances of this supposed cause having failed to operate when it might have been most expected to do so.

During the plague at Alexandria in 1835, which destroyed 9000 persons in that city, the exportation of cotton from the Government warehouses was never interrupted, though the plague was most destructive in those very buildings. It was loaded on English and other ships without any precautions whatever. Twenty-five ships, eight of which were infected with plague, conveyed cotton amounting to 31,000 bales to England. Nevertheless no case of plague is known to have occurred among the quarantine officers or others engaged in unloading these ships or disinfecting their cargoes in quarantine. Equally large quantities were exported to Marseilles and Trieste, and smaller quantities to other ports, with the same result. Further, no case of infection has occurred among quarantine officers or persons employed to disinfect goods, from this cause alone, either at Marseilles since 1720, or at any European lazaretto.² The conclusion is that the fear of importation of plague by merchandise coming from an infected country rests on no solid foundation.

By whatever means, there is no doubt that plague is

¹ See W. Wood, *History of Eyam*, London, 1848.

² Laidlaw, quoted in Prus, *Rapport*, p. 479.

diffused or "spreads" from one place to another, and that its spread is connected mediately or immediately, in most cases at least, with human intercourse. But this diffusion appears to take place as a rule slowly, and to be effected by the formation of new foci of contaminated atmosphere. Such foci on land will be inhabited houses, and the disease will creep in a gradual though irregular manner from house to house and street to street. It was so in London in 1665; and in Russia in 1878, as has been said, the disease was confined to one village for two months, though for great part of the time communication was perfectly open. In 1834 plague existed eight months at Alexandria before passing to Damietta and Mansoorah, though traffic was quite uninterrupted. These new foci of disease are doubtless mostly produced by persons infected with the disease, actually or in incubation, who form a contaminated atmosphere around them in a place previously healthy.

Transmission of the disease by sea may take place in the same manner,—a ship forming a focus of disease as easily as a house, and being obviously specially liable to concentrate the poison. It is by a floating atmosphere of plague, and not by casual contaminated objects, that the disease has been conveyed, when it has been, from one port to another of the Mediterranean. The reality of the mode of transmission is shown by the fact that between 1720 and 1846 twenty-five ships arrived at French and Italian ports with the plague among their crews; and in the case of those arriving at Marseilles (ten in number), which were carefully observed, there were several instances of plague being communicated in the lazaretto to surgeons and others, or to those placed in charge of the ships. Of these persons several died,—without, however, any extension of the disease to the town. From this it is clear that plague may be transmitted by ships, and may spread at the point to which it is conveyed, if the surrounding circumstances are favourable. In all these cases the ships had left the infected ports at a time when an epidemic of plague, and not merely sporadic cases, prevailed there. No similar facts are on record as to the importation of plague by ships to England,—the probable cause of this difference being the greater length of the voyage from the Levantine ports, and the precautions taken at those ports to prevent the shipment of infected persons or goods. Plague has never been brought to an English quarantine station.¹

In such cases it must remain undetermined whether the disease would have spread, had it not been interrupted by the quarantine. As we have seen, plague will often die out in the cases which convey it without spreading; and hence some have supposed (with Sydenham) that an "epidemic constitution" is necessary at any particular time and place in order that the disease should become general, but the practical value of this law is diminished by the fact that there is no means of recognizing the epidemic constitution except by the actual production of an epidemic.

Plague, like all similar diseases, and in a specially high degree, is subject to the law of periodicity. Even when it is most strictly endemic it seldom prevails continuously, but appears in definite outbreaks, or epidemics, with intervals in which there are either no cases of plague or only so-called sporadic cases. This may be partly due to the general law that the susceptibility of the population to a special disease is exhausted by an epidemic, partly to the immensely increased transmissibility of the disease caused by the increased number of cases, so that when once a certain stage of severity has been reached the disease progresses in a far more rapid ratio. In most epidemics of plague there is at one time a sudden and alarming increase

in mortality; but, by a law not yet understood, each epidemic is liable to a spontaneous decline, which is sometimes sudden. This may be connected with rise or fall in the temperature of the air, but is not always so. The disease may be dormant during the cold or hot weather (as the case may be) and reappear when the temperature is favourable again, but not necessarily. It is generally agreed that plague is transmissible to another country only when it is epidemic, and not from sporadic cases.

Incubation.—It is a very important question what time may elapse between a person receiving the poison and showing symptoms of the disease. The usual time of incubation appears to be from three to five days. In certain very malignant epidemics this period may be shortened, and, it is thought, reduced to even less than a day. In rare cases incubation may be prolonged to eight days. There are doubtful accounts of ten days' incubation. Generally a week's observation² would show whether a suspected person was really affected or no. It has been thought that articles contaminated by contact with plague patients may retain the power of communicating the disease for weeks, months, or even years; but of this there is no adequate proof.

Treatment.—No special line of treatment has proved efficacious in checking the disease once established. Special symptoms are treated in accordance with the ordinary rules of practice, and need not here be considered. Free ventilation appears to be of the greatest service in preventing the spread of the disease, and probably in promoting recovery.

Prevention.—There can be no doubt whatever of the efficacy of hygienic measures in rendering a locality unsuitable for the spread of plague. Such measures include, not only personal cleanliness, but especially the removal of all foul organic matters, good drainage, and prevention of overcrowding; all such measures might be looked upon by our readers generally as matters of course, but are quite unknown in most of the homes of plague. Since there is no doubt that plague may be carried from places where it prevails epidemically, measures to prevent such importation cannot be neglected. The best known of such measures is the system of quarantine first produced about 1480. See QUARANTINE. The efficiency of quarantine has been much discussed, and very strong opinions have been expressed for and against it. The subject is too large for discussion here; but it would appear that, while the system as originally applied in the Mediterranean, when traffic was comparatively slow and infrequent, and when European cities presented an extremely favourable soil for plague if introduced, was a real protection, the regulations have long ceased to correspond to the actual state of medical knowledge; and, in addition, it would be impossible to apply them to our crowded traffic. The alternative is a system of medical inspection of all arrivals in our ports, and strict isolation of ships in which plague has occurred or is suspected. Such a ship should then be treated as an infected house.

Prevention of the Spread of Plague.—When cases of plague have once occurred in a town or on board a ship in port, the house or ship should be emptied of its inhabitants, the sick removed to a hospital, the sound placed in an isolated building and subjected to observation for at least a week, or, better, ten days. The clothes of sick persons had better be burnt, their bedding and furniture completely disinfected. The house should in the meantime be rigidly closed until it has been disinfected. If these measures are taken in time, there can be no objection to allowing free emigration of the population. Isolation of the place by a "sanitary cordon" would only be possible

¹ Prus, *Rapport sur la Peste*, Paris, 1846, p. 133; *Report of Committee of House of Commons*, 1819, p. 101.

² Prus, *Rapport*, p. 196.

in very exceptional positions, and as a rule would aggravate, by overcrowding, the intensity of the disease within.

History of the Plague.—The first historical notice of the plague is contained in a fragment of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the *Collections of Oribasius*.¹ Rufus speaks of the buboes called pestilential as being specially fatal, and as being found chiefly in Libya, Egypt, and Syria. He refers to the testimony of a physician Dionysius, who lived probably in the 3d century B.C. or earlier, and to Dioscorides and Posidonius, who fully described these buboes in a work on the plague which prevailed in Libya in their time. Whatever the precise date of these physicians may have been, this passage shows the antiquity of the plague in northern Africa, which for centuries was considered as its home. The great plague referred to by Livy (i.e., Epitome) an dmore fully by Orosius (*Histor.*, iv. 11) was probably the same, though the symptoms are not recorded. It is reported to have destroyed a million of persons in Africa, but is not stated to have passed into Europe.

It is not till the 6th century of our era, in the reign of Justinian, that we find bubonic plague in Europe, as a part of the great cycle of pestilence, accompanied by extraordinary natural phenomena, which lasted fifty years, and is described with a singular misunderstanding of medical terms by Gibbon in his forty-third chapter. The descriptions of the contemporary writers Procopius, Evagrius, and Gregory of Tours are quite unmistakable.² The plague of Justinian began at Pelusium in Egypt in 542 A.D.; it spread over Egypt, and in the same or the next year passed to Constantinople, where it carried off 10,000 persons in one day, with all the symptoms of bubonic plague. It appeared in Gaul in 546, where it is described by Gregory of Tours with the same symptoms as *lurs inguinaria* (from the frequent seat of buboes in the groin). In Italy there was a great mortality in 543, but the most notable epidemic was in 565, which so depopulated the country as to leave it an easy prey to the Lombards. In 571 it is again recorded in Liguria, and in 590 a great epidemic at Rome is connected with the pontificate of Gregory the Great. But it spread in fact over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were the plague cannot now be said; but it is possible the pestilences in England chronicled by Bede in the years 664, 672, 679, and 683 may have been of this disease, especially as in 690 *pestis inguinaria* is again recorded in Rome. For the epidemics of the succeeding centuries we must refer to more detailed works.³

It is impossible, however, to pass over the great cycle of epidemics in the 14th century known as the Black Death. Whether in all the pestilences known by this name the disease was really the same may admit of doubt, but it is clear that in some at least it was the bubonic plague. Contemporary observers agree that the disease was introduced from the East; and one eye-witness, Gabriel de Mussis, an Italian lawyer, traced, or indeed accompanied, the march of the plague from the Crimea (whither it was said to have been introduced from Tartary) to Genoa, where with a handful of survivors of a Genoese expedition he landed probably at the end of the year 1347. He narrates how the few that had themselves escaped the pest transmitted the contagion to all they met.⁴ Other accounts, especially old Russian chronicles, place the origin of the disease still further to the east in Cathay (or China), where, as is confirmed to some extent by Chinese records, pestilence and destructive inundations are said to have destroyed the enormous number of thirteen millions. It appears to have passed by way of Armenia into Asia Minor and thence to Egypt and northern Africa. Nearly the whole of Europe was gradually overrun by the pestilence. It reached Sicily in 1346, Constantinople, Greece, and parts of Italy early in 1347, and towards the end of that year Marseilles. In 1348 it attacked Spain, northern Italy and Rome, eastern Germany, many parts of France including Paris, and England; from England it is said to have been conveyed to the Scandinavian countries. In England the western counties were first invaded early in the year, and London in November. In 1349 we hear of it in the midlands; and in subsequent years, at least till 1357, it prevailed in parts of the country, or generally, especially in the towns. In 1352 Oxford

lost two-thirds of her academical population. The outbreaks of 1361 and 1368, known as the second and third plagues of the reign of Edward III., were doubtless of the same disease, though by some historians not called the black death. Scotland and Ireland, though later affected, did not escape.

The nature of this pestilence has been a matter of much controversy, and some have doubted its being truly the plague. But when the symptoms are fully described they seem to justify this conclusion, one character only being thought to make a distinction between this and Oriental plague, viz., the special implication of the lungs as shown by spitting of blood and other symptoms. Guy de Chauliac notes this feature in the earlier epidemic at Avignon, not in the later. Moreover, as this complication was a marked feature in certain epidemics of plague in India, the hypothesis has been framed by Hirsch that a special variety of plague, *pestis Indica*, still found in India, is that which overran the world in the 14th century. But the same symptoms (hæmoptysis) have been seen, though less notably, in many plague epidemics, even in the latest, that in Russia in 1878-79, and, moreover, according to the latest accounts, are not a special feature of Indian plague. According to Surgeon-General Francis (*Trans. Epidem. Soc.*, vol. v. p. 398) "hæmorrhage is not an ordinary accompaniment" of Indian plague, though when seen it is in the form of hæmoptysis. It seems, therefore, impossible to make a special variety of Indian plague, or to refer the black death to any such special form. Gabriel de Mussis describes it even in the East, before its arrival in Europe, as a bubonic disease.

The mortality of the black death was, as is well known, enormous. It is estimated in various parts of Europe at two-thirds or three-fourths of the population in the first pestilence, in England even higher, but some countries were much less severely affected. Hecker calculates that one-fourth of the population of Europe, or 25 millions of persons, died in the whole of the epidemics. It is hardly necessary to dwell upon the social results of this terrible mortality. In England great part of the country remained untilled, and the deficiency of labourers was such as to cause a sudden rise of wages, which, in spite of attempts to check it by legislation, is thought to have effected the final emancipation of the labouring class. On the other hand a great transfer of property to the church took place, with what results is well known.

In the 15th century the plague recurred frequently in nearly all parts of Europe. In the first quarter it was very destructive in Italy, in Spain (especially Barcelona and Seville), in Germany, and in England, where London was severely visited in 1400 and 1406, and again in 1428. In 1427 80,000 persons died in Dantzic and the neighbourhood. In 1438-39 the plague was in Germany, and its occurrence at Basel was described by Aneas Sylvius, afterwards Pope Pius II. In 1448-50 Italy (Kircher), Germany (Lersch, from old chronicles), France, and Spain were ravaged by a plague supposed to have arisen in Asia, scarcely less destructive than the black death. England was probably seldom quite free from plague, but the next great outbreak is recorded in 1472 and following years. In 1466 40,000 persons died of plague in Paris; in 1477-85 the cities of northern Italy were devastated, and in 1485 Brussels. In the fifteenth year of Henry VII. (1499-1500) a severe plague in London caused the king to retire to Calais.

The 16th century was not more free from plague than the 15th. Simultaneously with a terrible pestilence which is reported to have nearly depopulated China, plague prevailed over Germany, Holland, Italy, and Spain in the first decade of the century, and revived at various times in the first half. In 1529 there was plague in Edinburgh; in London in 1537-39, and again 1547-48; and also in the north of England, though probably not absent before. Some of the epidemics of this period in Italy and Germany are known by the accounts of eminent physicians, as Vocho, Fracastor, Mercurialis, Borgarucci, Ingrassia, Massaria, Amici, &c.,⁵ whose writings are important because the question of contagion first began to be raised, and also plague had to be distinguished from typhus fever, which began in this century to appear in Europe.

The epidemic of 1563-64 in London and England was very severe, a thousand dying weekly in London. In Paris about this time plague was an everyday occurrence, of which some were less afraid than of a headache (Borgarucci). In 1570 200,000 persons died in Moscow and the neighbourhood, in 1572 50,000 at Lyons; in 1568 and 1574 plague was at Edinburgh, and in 1570 at Newcastle. When, however, in 1575 a new wave of plague passed over Europe, its origin was referred to Constantinople, whence it was said to have spread by sea to Malta, Sicily, and Italy, and by land through the Austrian territories to Germany. Others contended that the

Regno di Sicilia*, 1575-76, 4to, Palermo, 1576-77; A. Massaria, *De Peste*, Ven., 1597; Diomedes Amicus, *Tres traciatus*, Ven., 1599, 4to; Victor de Bonagenitibus, *Decem Problemata de Peste*, Ven., 1556, 8vo; Georgius Agricola, *De Peste libris tres*, Basel, 1554, 8vo. The works of English physicians of this period are of little medical value; but Lodge's *Treatise of the Plague* (London, 1608) deserves mention.

disease originated locally; and, indeed, considering previous history, no importation of plague would seem necessary to explain its presence in Europe. Italy suffered severely (Venice, in 1576, lost 70,000); the north of Europe not less, though later; London in 1580-82. In 1585 Breslau witnessed the most destructive plague known in its history. The great plague of 1592 in London seems to have been a part of the same epidemic, which was hardly extinguished by the end of the century, and is noted in London again in 1599. On the whole, this century shows a decrease of plague in Europe.

In the first half of the 17th century plague was still prevalent in Europe, though considerably less so than in the Middle Ages. In the second half a still greater decline is observable, and by the third quarter the disease had disappeared or was disappearing from a great part of western Europe. The epidemics in England will be most conveniently considered in one series. From this time onwards we have the guidance of the "Bills of Mortality" issued in London, which, though drawn up on the evidence of ignorant persons, are doubtless roughly true. The accession of James I. in 1603 was marked by a very destructive plague which killed 38,000 in London. In this and subsequent years the disease was widely diffused in England—for instance, Oxford, Derbyshire, Newcastle. It prevailed at the same time in Holland, and had done so some years previously in northern Germany. In the same year (1603) one million persons are said to have died of plague in Egypt. This plague is said to have lasted eight years in London. At all events in 1609 we have the second great plague year, with a mortality of 11,785. After this there is a remission till about 1620, when plague again began to spread in northern Europe, especially Germany and Holland, which was at that time ravaged by war. In 1625 (the year of the siege of Breda in Holland) is the third great London plague with 35,417 deaths,—though the year 1624 was remarkably exempt, and 1626 nearly so. In 1630 was the great plague of Milan, described by Ripamonti.¹ In 1632 a severe epidemic, apparently plague, was in Derbyshire. 1636 is the fourth great plague year in London with a mortality of 10,400, and even in the next year 3082 persons died of the same disease. The same year 7000 out of 20,000 inhabitants of Newcastle died of plague; in 1635 it was at Hull. About the same time, 1635-37, plague was prevalent in Holland, and the epidemic of Nimeguen is celebrated as having been described by Diemerbroeck, whose work (*Tractatus de Peste*, 4to, 1641-65) is one of the most important on the subject. The English epidemic was widely spread and lasted till 1647, in which year, the mortality amounting to 3597, we have the fifth epidemic in London. The army diseases of the Civil Wars were chiefly typhus and malarial fevers, but plague was not unknown among them, as at Wallingford Castle (Willis, "Of Feavers," *Works*, ed. 1681, p. 131) and Dunstun Castle. From this time till 1664 little was heard of plague in England, though it did not cease on the Continent. In Ireland it is said to have been seen for the last time in 1650.²

In 1656 one of the most destructive of all recorded epidemics in Europe raged in Naples; it is said to have carried off 300,000 persons in the space of five months. It passed to Rome, but there was much less fatal, making 14,000 victims only—a result attributed by some to the precautions and sanitary measures introduced by Cardinal Gastaldi, whose work, a splendid folio, written on this occasion (*Tractatus de avertenda et profiganda peste politico-legalis*, Bologna, 1684) is historically one of the most important on the subject of quarantine, &c. Genoa lost 60,000 inhabitants from the same disease, but Tuscany remained untouched. The comparatively limited spread of this frightful epidemic in Italy at this time is a most noteworthy fact. Minorca is said to have been depopulated. Nevertheless the epidemic spread in the next few years over Spain and Germany, and a little later to Holland, where Amsterdam in 1663-64 was again ravaged with a mortality given as 50,000, also Rotterdam and Haarlem. Hamburg suffered in 1664.

The Great Plague of London.—The preceding enumeration will have prepared the reader to view the great plague of 1664-65 in its true relation to others, and not as an isolated phenomenon. The preceding years had been unusually free from plague, and it was not mentioned in the bills of mortality till in the autumn of 1664 (November 2d) a few isolated cases were observed in the parishes of St Giles and St Martin's, Westminster, and a few occurred in the following winter, which was very severe. About May 1665 the disease again became noticeable, and spread, but somewhat slowly. Boghurst, a contemporary doctor, notices that it crept down Holborn and took six months to travel from the western suburbs (St Giles) to the eastern (Stepney) through the city. The mortality rapidly rose from 43 in May to 590 in June, 6137 in July, 17,036 in August, 31,159 in September, after which it began to decline. The total number of deaths from plague in that year, according to the bills of mortality was 68,596, in a population estimated at 460,000.³

out of whom two-thirds are supposed to have fled to escape the contagion. This number is likely to be rather too low than too high, since of the 6432 deaths from spotted fever many were probably really from plague, though not declared so to avoid painful restrictions. In December there was a sudden fall in the mortality which continued through the winter; but in 1666 nearly 2000 deaths from plague are recorded.

According to some authorities, especially Hodges, the plague was imported into London by bales of merchandise from Holland, which came originally from the Levant; according to others it was introduced by Dutch prisoners of war; but Boghurst regarded it as of local origin. It is in favour of the theory that it spread by some means from Holland that plague had been all but extinct in London for some seventeen years, and prevailed in Holland in 1663-64. But from its past history and local conditions, London might well be deemed capable of producing such an epidemic. In the bills of mortality since 1603 there are only three years when no deaths from plague are recorded. The uncleanness of the city was comparable to that of Oriental cities at the present day, and, according to contemporary testimony (Garencières, *Angliæ Flagellum*, London 1647, p. 85), little improved since Erasmus wrote his well-known description. The spread of the disease only partially supported the doctrine of contagion, as Boghurst says:—"The disease spread not altogether by contagion at first, nor began only at one place and spread further and further as an eating sore doth all over the body, but fell upon several places of city and suburbs like rain." In fact dissemination seems to have taken place, as usual, by the conversion of one house after another into a focus of disease, a process favoured by the fatal custom of shutting up infected houses with all their inmates, which was not only almost equivalent to a sentence of death on all therein, but caused a dangerous concentration of the poison. The well-known custom of marking such houses with a red cross and the legend "God have mercy upon us!" was no new thing: it is found in a proclamation in the possession of the present writer dated 1641; and it was probably older still. Hodges testifies to the futility and injurious effects of these regulations. The lord mayor and magistrates not only carried out the appointed administrative measures, but looked to the cleanliness of the city and the relief of the poor, so that there was little or no actual want; and the burial arrangements appear to have been well attended to. The college of physicians, by royal command, put forth such advice and prescriptions as were thought best for the emergency. But it is clear that neither these measures nor medical treatment had any effect in checking the disease. Early in November with colder weather it began to decline; and in December there was so little fear of contagion that those who had left the city "crowded back as thick as they fled." As has often been observed in other plague epidemics, sound people could enter infected houses and even sleep in the beds of those who had died of the plague "before they were even cold or cleansed from the stench of the diseased" (Hodges). The symptoms of the disease being such as have been generally observed need not be here considered. The disease was, as always, most destructive in squalid, dirty neighbourhoods and among the poor, so as to be called the "poor's plague." Those who lived in the town in barges or ships did not take the disease; and the houses on London Bridge were but little affected. Of those doctors who remained in the city some eight or nine died, not a large proportion. Some had the rare courage to investigate the mysterious disease by dissecting the bodies of the dead. Hodges implies that he did so, though he left no full account of his observations. Dr George Thomson, a chemist and a disciple of Van Helmont, followed the example, and nearly lost his life by an attack which immediately followed.⁴

The plague of 1665 was widely spread over England, and was generally regarded as having been transmitted from London, as it appeared mostly later than in the metropolis, and in many cases the importation by a particular person could be traced. Places near London were earliest affected, as Brentford, Greenwich, Deptford; but in July or August 1665 it was already in Southampton, Sunderland, Newcastle, &c. A wider distribution occurred in the next year. Oxford entirely escaped, though the residence of the court and in constant communication with London. The exemption was attributed to cleanliness and good drainage.

After 1666 there was no epidemic of plague in London or any part of England, though sporadic cases appear in bills of mortality up to 1679; and a column filled up with "0" was left till 1703,

⁴ On the plague of 1665 see Nath. Hodges, *Loimologia sive Pestis nuperæ apud populum Londinensem narratio*, London, 1672, 8vo.—in English by Quincy, London, 1720 (the chief authority); *Λοιμογραφία, or an Experimental Relation of the last Plague in the City of London*, by William Boghurst, apothecary in St Giles's-in-the-Fields, London, 1666,—a MS. in British Museum (Sloane 349), containing important details; George Thomson, *ΑΙΟΜΟΤΟΜΙΑ, or the Pest Anatomized*, 8vo, London, 1666; Sydenham, "Febris pestilentialis et pestis annorum 1665-66," *Opera*, ed. ³ Graunt, *Observations on the Bills of Mortality*, 3d ed., London, 1665.

when it finally disappeared. The disappearance of plague in London was attributed to the Great Fire, but no such cause existed in other cities. It has also been ascribed to quarantine, but no effective quarantine was established till 1720, so that the cessation of plague in England must be regarded as spontaneous.

But this was no isolated fact. A similar cessation of plague was noted soon after in the greater part of western Europe. In 1666 a severe plague raged in Cologne and on the Rhine, which was prolonged till 1670 in the district. In the Netherlands there was plague in 1667-69, but there are no definite notices of it after 1672. France saw the last plague epidemic in 1668, till it reappeared in 1720. In the years 1675-84 a new plague epidemic appeared in North Africa, Turkey, Poland, Hungary, Austria, and Germany, progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 was very severe, causing 76,000 or probably more deaths. Prague in 1681 lost 83,000 by plague. Dresden was affected in 1680, Magdeburg and Halle in 1682,—in the latter town with a mortality of 4397 out of a population of about 10,000. Many North German cities suffered about the same time; but in 1683 the plague disappeared from Germany till the epidemic of 1707. In Spain it ceased about 1681; in Italy certain cities were attacked till the end of the century, but not later (Hirsch).

Plague in the 18th Century.—At the beginning of this period plague was very prevalent in Constantinople and along the Danube. In 1703 it caused great destruction in the Ukraine. In 1704 it began to spread through Poland, and later to Silesia, Lithuania, Prussia, and a great part of Germany and Scandinavia. In Prussia and Lithuania 283,000 persons perished; Dantzic, Hamburg, and other northern cities suffered severely. Copenhagen was attacked in 1710. In Stockholm there was a mortality of 40,000. Certain places near Brunswick (10° E. long.) marked the western limit of the epidemic; and cholera was arrested at the same spot in later years (Haeser).

At the same time the plague spread westward from the Danube to Transylvania and Styria, and (1713) appeared in Austria and Bohemia, causing great mortality in Vienna. Thence it passed to Prague and Ratisbon—to the former, possibly to the latter, almost certainly conveyed by human intercourse. This city (12° E. long.) was the western limit reached in this year. Haeser states that the plague disappeared everywhere in Europe after the great hurricane of February 27, 1714.

In 1717 plague raged severely in Constantinople; and in 1719 it made a fresh progress westwards into Transylvania, Hungary, Galicia, and Poland, but not farther (about 20° E. long.). It thus appears that each successive invasion had a more easterly western limit, and that the gradual narrowing of the range of plague, which began in the 17th century, was still going on.

This process suffered a temporary interruption by the outbreak of plague of southern France in 1720-22. In 1720 Marseilles became affected with an epidemic plague, the origin of which was attributed by some to contagion through the ship of a Captain Chataud which arrived, May 20, 1720, from Syria, where plague at that time prevailed, though not epidemically when he sailed. Six of the crew had died on the voyage to Leghorn, but the disease was declared not to be plague. Cases of plague occurred, however, on the ship, and on June 22 among porters unloading the cargo. Hence, according to believers in contagion, the disease passed to families in the "old town," the poorest and unhealthiest quarter. In the meantime other ships had arrived from Syria, which were put in quarantine. According to others the plague arose in Marseilles from local causes; and recently discovered data show that suspicious cases of contagious disease occurred in the town before the arrival of Chataud's ship.¹ Opinions were divided, and the evidence appears even now nearly balanced, though the believers in contagion and importation gained the victory in public opinion. The pestilence was fearfully severe. Thousands of unburied corpses filled the streets, and in all 40,000 to 60,000 persons were carried off. In December 1721 the plague passed away, though isolated cases occurred in 1722. It passed to, or at least broke out in, Arles and Aix in 1720, causing great mortality, but in Toulon not till 1721, when it destroyed two-thirds of the population. The epidemic spread generally over Provence, but not to other parts of France, notwithstanding that, as confessed by D'Antrechaus, consul of Toulon, a believer in the exclusive power of contagion, there were abundant opportunities. The disease was in fact, as in other cases, self-limited. In all 87,659 persons are said to have died out of a population of nearly 250,000.²

This great epidemic caused a panic in England, which led to the introduction (under Mead's advice) of quarantine regulations, never previously enforced, and also led to the publication of many

pamphlets, &c., beside Mead's well-known *Discourse on Pestilential Contagion* (London, 1720).

Plague in Sicily in 1743.—An outbreak of plague at Messina in 1743 is important, not only for its fatality, but as one of the strongest cases in favour of the theory of imported contagion. Messina had been free from plague since 1624, and the Sicilians prided themselves on the rigour of the quarantine laws which were thought to have preserved them. In May 1743 a vessel arrived from Corfu, on board of which had occurred some suspicious deaths. The ship and cargo were burnt, but soon after cases of a suspicious form of disease were observed in the hospital and in the poorest parts of the town; and in the summer a fearful epidemic of plague developed itself which destroyed 40,000 or 50,000 persons, and then became extinct without spreading to other parts of Sicily.

Spread of Plague from the East.—Independent of the episodes of Marseilles and Messina, the spread of plague from the East continued to exhibit the above-mentioned law of limitation. In 1738-44 the disease was in the Ukraine, Hungary, the borders of Carniola, Moravia, and Austria, extending along the Carpathians as far as Poland (20° E. long.), and also in Bukowina (25° E. long.). It lasted till 1745, and then disappeared from those parts for fifteen years. In 1755-57 plague prevailed in parts of European Turkey, whence it on one occasion extended into Transylvania, in the neighbourhood of Cronstadt, where it was checked (25° 5' E. long.).³

In 1770 a destructive plague arose in Moldavia during the Russo-Turkish War, and shortly afterwards in Wallachia, apparently endemic in the former country at least. It affected also Transylvania and part of Hungary, and still more severely Poland, but was confined to Podolia, Volhynia, the Ukraine, and the eastern part of Galicia (25° E. long.), not even penetrating as far as Warsaw. After destroying, it is said, 300,000 persons, and without being checked by any quarantine regulations, the plague died out finally in March 1771, being remarkable for its short duration and spontaneous limitation (Haeser).

In another direction the plague spread over Little Russia in 1770, and desolated Kieff, while in the next year it broke out in Moscow and produced one of the most destructive epidemics of modern times. More than 50,000 persons, nearly one-fourth of the population, were carried off.⁴

The remaining European plague-epidemics of the 18th century were inconsiderable, but on that very account noteworthy. Transylvania was again affected in 1785, Slavonia and Livonia (a district of eastern Galicia) in 1795-96 (25° E. long.), Volhynia in 1798. The disease, while reappearing in the seats of the terrible earlier epidemics, was more limited in its range and of shorter duration.⁵ An epidemic in Dalmatia in 1783-84 is noteworthy in connexion with later outbreaks in the same region. In the last years of the century (1799-1800) there was a new epidemic in Syria and Egypt, where it affected the French and afterwards the English army.

Plague in the 19th Century.—This history divides itself naturally into two periods—1800-1845, and 1853 to the present time.

1800-1845.—Plague appeared at Constantinople in 1802-3, about the same time in Armenia (Kars), and in 1801 in Baghdad. It had prevailed since 1798 in Georgia and the Caucasus, and in 1803-6 began to spread from the north of the Caucasus into Russia, till in 1806 it was established at or near Astrakhan, and in 1807 reached Zareff, 200 miles higher up the Volga. These localities are interesting as being near those where plague appeared in 1877-78. It is also said to have entered the government of Saratoff, but probably no great distance.⁶ The plague remained in the Caucasus and Georgia till 1819 at least. In 1828-31 it was in Armenia, and again in 1840-43, since which time it has not been heard of in that country.

In 1808 plague was at Constantinople, in 1809 at Smyrna. In 1812 was a more general epidemic affecting these places and also Egypt. An outbreak at Odessa is supposed to have been brought from Constantinople and thence to have passed to Transylvania. In 1813 a severe plague at Bucharest is supposed to have been brought from Constantinople. About the same time plague prevailed in Bosnia, and is supposed to have passed thence to Dalmatia in 1815. In 1814-15 it again appeared in Egypt, and once more invaded the continent of Europe in Albania and Bosnia. Two insular outbreaks, Malta in 1813 and Corfu in 1815, attracted much attention as being both thought to be cases of importation by sea-traffic,⁷ and there seems good reason for this opinion.

A panic spread through Europe in 1815 in consequence of an outbreak in Noja on the eastern coast of Italy, its last appearance

in that country. According to one view it was imported from the opposite coast of Dalmatia, though no definite history of contagion was established; according to others, it originated endemically in that place. It remained, however, strictly confined to a small district, perhaps in consequence of the extraordinarily rigorous measures of isolation adopted by the Italian Government. In 1828 an isolated epidemic appeared in Greece in the Morea, supposed to have been brought by troops from Egypt.¹ In 1824-25 an outbreak took place at Tutchkoff in Bessarabia; the town was strictly isolated by a military cordon and the disease did not spread.² Cronstadt in Transylvania was the scene of a small outbreak in 1828, which was said to be isolated by similar measures (Lorinser). A far more serious epidemic was connected with the campaign of the Russian army against Turkey in 1828-29. Moldavia, Wallachia, and Bessarabia were widely affected; the disease broke out also in Odessa and the Crimea, and isolated cases occurred in Transylvania. The most northerly points reached by the plague were near Czernowitz on the frontier of Bessarabia, and Bukowina, and its limitation was as before attributed to the Russian and Austrian military cordons.

In 1831 another epidemic occurred in Constantinople and Roumelia; in 1837 again in Roumelia, and in Odessa,—its last appearance in those regions, and the last on the European continent except an isolated outbreak in Dalmatia in 1840, and one in Constantinople in 1841.³

The plague-epidemics in Egypt between 1833 and 1845, when it was last observed in that country, are very important in the history of plague, since the disease was almost for the first time scientifically studied in its home by skilled European physicians, chiefly French. The disease was found to be less contagious than reported to be by popular tradition, and most of the French school went so far as to deny the contagiousness of the disease altogether. The epidemic of 1834-35 was not less destructive than many of those notorious in history; but in 1844-45 the disease disappeared, and it has never been seen since in the country which was for centuries regarded as its native home. This result can hardly be attributed to quarantine, though it is probable that increased attention to sanitary measures under the influence of educated medical officials may have had much to do with it. But on the large scale it is a part of the great eastward recession of the plague, which is an undoubted fact, however it is to be explained. In 1840 Dalmatia (17° E. long.), in 1841 Constantinople (29° E. long.), in 1843-44 the eastern parts of Egypt (31° E. long.), were the western boundaries of plague. The same law has, with one notable exception, been observed since.

1853-84.—Since the apparent extinction of plague in Egypt in 1845, it has appeared in several points of Asia and Africa, and once in Europe.

In 1853 plague appeared in a district of western Arabia, the Asir country in North Yemen, and it is known to have occurred in the same district in 1815, as it did afterwards in 1874 and 1879. In 1874 the disease extended within four days' march of Mecca. From the scantiness of population the mortality has not been great, but it is clear that this is one of the endemic seats of plague.⁴

In June 1858 intelligence was received in Constantinople of an outbreak of disease at the small town Benghazi, in the district of Barca, province of Tripoli, North Africa, which though at first misunderstood was clearly bubonic plague. From later researches there is reason to believe that it commenced in 1856 or in 1855. The disease did not spread, and ceased in the autumn, to return with less violence in 1859, when it died out. In the autumn of 1873 it returned, but apparently came again to a spontaneous termination. At all events it has not been heard of since.⁵

After the epidemic of Benghazi in 1856-59, plague was next heard of in the district of Maku, in the extreme north-west of Persia in November 1863. It occurred in a scattered population, and the mortality was not absolutely large.⁶

In 1867 an outbreak of plague was reported in Mesopotamia (Iraq), among the marshes of Hindieh bordering on the lower Euphrates; and, as it has prevailed at intervals up to the present time in the same country, great importance attaches to its history. The epidemic began in December 1866 (or probably earlier) and ceased in June 1867. But numerous cases of non-fatal mild bubonic disease (mild plague or *pestis minor*) occurred both before and after the epidemic, and according to Tholozan similar cases had been observed nearly every year from 1856 to 1865.⁷

The next severe epidemic of plague in Irak began in December 1873. But facts collected by Tholozan show that *pestis minor*, or sporadic cases of true plague, had appeared in 1868 and subsequent years. The outbreak of 1873-74 began about 60 miles from the origin of that of 1867. It caused a much greater mortality and extended over a much wider area than that of 1867, including the

towns of Kerbela and Hilleh. After a short interval it reappeared at Divanieh in December 1874, and spread over a much wider area than in the previous epidemics. This epidemic was carefully studied by Surgeon-Major Colvill.⁸ He estimated the mortality at 4000. The epidemic ceased in July, but broke out again early in 1876, and in this year extended northwards to Baghdad and beyond. The whole area now affected extended 250 miles from north-west to south-east, and the total number of deaths was believed to be 20,000. In 1877 plague also occurred at Shuster in south-west Persia, probably conveyed by pilgrims returning from Irak, and caused great mortality.

After its customary cessation in the autumn (a pause attributed as before to the efficiency of quarantine regulations), the epidemic began again in October 1876, though sporadic cases occurred all the summer. The disease appeared in 1877 in other parts of Mesopotamia also with less severity than in 1876, but over a wider area, being now announced at Samara, a town 70 miles above Baghdad on the Tigris. Since then the existence of plague in Baghdad or Mesopotamia has not been announced till the year 1884, when accounts again appeared in the newspapers, and in July the usual official statement occurs that the plague has been stamped out. The above account of plague in Irak is the most complete history of a succession of epidemics in one country which we have had of late years.

To complete the history of plague in Persia it should be stated that in 1870-71 it appeared in a district of Mukri in Persian Kurdistan to the south of Lake Urumiah (far removed from the outbreak of 1863). The epidemic appears, however, to have died out in 1871, and no further accounts of plague there have been received. The district had suffered in the great epidemic of plague in Persia in 1829-35. In the winter 1876-77 a disease which appears to have been plague appeared in two villages in the extreme north of the province of Khorasan, about 25 leagues from the south-east angle of the Caspian Sea. In March 1877 plague broke out in Resht, a town of 20,000 inhabitants, in the province of Ghilan, near the Caspian Sea at its south-west angle, from which there is a certain amount of trade with Astrakhan. In 1832 a very destructive plague had carried off half the inhabitants. In 1877 the plague was very fatal. From March to September 4000 persons were calculated to have died. The disease continued till the spring of 1878. In 1877 there was a doubtful report of the same disease at Astrabad, and also in some parts near the Perso-Afghan frontier. In 1878 plague again occurred in Kurdistan in the district of So-uj-Bulak, said by Dr Tholozan to be the same as in the district of Mukri where it occurred in 1870-71. These scattered outbreaks of plague in Persian territory are the more remarkable because that country has been generally noted for its freedom from plague (as compared with Asiatic Turkey and the Levant).

It has since been known that a few cases of plague occurred in January 1877 at Baku on the west shore of the Caspian, in Russian territory.⁹

The last outbreak of plague on European soil was that of 1878-79 on the banks of the Volga, which caused a panic throughout Europe.¹⁰ It is now known that in the summer of 1877 a disease prevailed in several villages in the neighbourhood of Astrakhan and in the city itself, which was clearly a mild form of plague (*pestis minor*). It caused no deaths (or only one due to a complication) and died out apparently spontaneously. An official physician, Dr Kastorsky, who investigated the matter for the Government, declared the disease to be identical with that prevailing in the same year at Resht in Persia; another physician, Dr Janizky, even gave it the name of *pestis nostras*. In October 1878 some cases appeared in the *stanitza* or Cossack military settlement of Vetlanka, 180 miles from Astrakhan on the right bank of the Volga, which seem to have puzzled the physicians who first observed them, but on November 30th were recognized as being but the same mild plague as had been observed the year before near Astrakhan by Dr Döppner, chief medical officer of the Cossacks of Astrakhan. His report on the epidemic is the only original one we have. At the end of November¹¹ the disease became suddenly more severe, and most of those attacked died; and from the 21st December it became still more malignant, death occurring in some cases in a few hours, and without any buboes being formed. No case of recovery was known in this period. At the end of the year it rapidly declined, and in the first weeks of January still more so. The last death was on January 24. In the second half of December, when the disease had already lasted two months, cases of plague occurred in several neighbouring villages, all of an extremely malignant type, so that in some places all who were attacked died. In most of these cases the disease began with persons who had been at Vetlanka, though this was not universally established. The inhabitants of these

¹¹ The dates are all reduced to new style.

villages, terrified at the accounts from Vetlanka, strictly isolated the sick, and thus probably checked the spread of the disease. But it evidently suffered a spontaneous decline. By the end of January there were no cases left in the district except at one village (Selitrennoye), where the last occurred on the 9th February. The total number of cases in Vetlanka, out of a population of about 1700, was 417, of whom 362 died. In the other villages there were about 62 deaths from plague, and not more than two or three cases of recovery. In consequence of the alarm excited by this last appearance of plague upon European soil, most European Governments sent special commissions to the spot. The British commissioners were Surgeon-Major Colvill and the present writer, who, like all the foreign commissioners, reached the spot when the epidemic was over. With respect to the origin of this epidemic, the possibility of its having originated on the spot, as in Resht and on the Euphrates in very similar situations, is not to be denied. An attempt was made to show that the contagion was brought home by Cossacks returning from the Turkish War, but on absolutely no evidence. In the opinion of the writer the real beginning of the disease was in the year 1877, in the vicinity of Astrakhan, and the sudden development of the malignant out of a mild form of the disease is no more than has been observed in other places. The Astrakhan disease may have been imported from Resht or Baku, or may have been caused concurrently with the epidemics of these places by some cause affecting the basin of the Caspian generally. But the conditions under which these mild or miasmatic forms of plague are spread are as yet unknown.

Plague in India.—It used to be held as a maxim that plague never appeared east of the Indus; nevertheless it has been observed during this century in more than one distinct centre in India. So long ago as 1815 the disease appeared in Guzerat, Kattywar, and Cutch, "after three years of severe famine." It reappeared early next year, in the same locality, when it extended to Sind as far as Hyderabad, and in another direction south-east as far as Ahmedabad and Dhollerah. But it disappeared from these parts in 1820 or early in 1821, and was not heard of again till July 1836, when a disease broke out into violence at the town of Pali in Marwar in Rajputana. It spread from Pali to the province of Meywar, but died out spontaneously in the hot season of 1837, and has never been heard of again in that part of India. The origin of these two epidemics was obscure. No importation from other countries could be traced.

In 1823 (though not officially known till later) an epidemic broke out at Kedarnath in Gurwhal, a sub-district of Kumaon on the south-west of the Himalayas, on a high situation. In 1834 and 1836 other epidemics occurred, which at last attracted the attention of Government. In 1849–50, and again in 1852, the disease raged very severely and spread southward. In 1853 Dr Francis and Dr Pearson were appointed a commission to inquire into the malady. In 1876–77 another outbreak occurred, since which time no accounts of the epidemic have been received. The symptoms of this disease, called *maha murree* by the natives, are precisely those of Oriental plague. The feature of blood-spitting, to which much importance has been attached, appears to be not a common one. A very remarkable circumstance is the death of animals (rats, and more rarely snakes), which occurs at the outbreak of an epidemic. The rats bring up blood, and the body of one examined after death by Dr Francis showed an affection of the lungs. *Maha murree* is intensely communicable, but does not show much tendency to spread, since pilgrims who visit the mountain shrines are not affected and do not convey the disease. It is doubtless connected with uncleanness and poverty, but Dr Francis believes that the poison exists in the soil, which becomes more and more contaminated with it. The disease is pretty clearly endemic, not imported.¹

It is remarkable that of late years reports have come of the occurrence of Oriental plague in China. It has been observed in the province of Yunnan since 1871, and also at Pakhoi, a port in the Tong-king Gulf, as lately as 1882,—but said to have prevailed there at least fifteen years. In Yunnan it appears to be endemic, though there are rumours of its having been brought from Burmah, and become more noticeable after the suppression of a rebellion in that province. The climate is temperate and the country partly mountainous. Some regard the disease as being conveyed from Pakhoi to Yunnan. In both places the symptoms were the same, of undoubted bubonic plague. It has always been noticed, as in India, that rats leave their holes and die at the beginning of an epidemic; and the same mortality has been observed among cats, dogs, cattle, ponies, deer, &c. At Pakhoi it recurs nearly every year.² Uncleanly habits have much to do with fostering the disease.

It thus appears that at the present time plague exists, or has existed within ten years, in the following parts of the world:—(1) Benghazi, Africa; (2) Persian Kurdistan; (3) Irak, on the Tigris and Euphrates; (4) the Asir country, western Arabia; (5) on the lower Volga, Russia; (6) northern Persia and the shores of the Caspian; (7) Kumaon and Gurwhal, India; (8) Yunnan and Pakhoi, China. Except Benghazi all these places show an eastward recession as compared with the old seats of plague known to us.

PLAICE (*Pleuronectes platessa*), a species of Flat-fish, common on the coasts of northern Europe from Iceland to the Bay of Biscay. It is readily recognized by the yellow or orange-coloured spots which are placed in a row along the dorsal and anal fins, and scattered over the body. The eyes are on the right side, and the teeth in the jaws compressed and truncate. The scales are minute and smooth. In the dorsal fin from sixty-seven to seventy-seven rays may be counted, in the anal from fifty to fifty-seven. Plaice, like other flat-fishes, prefer a sandy flat bottom to a rocky ground, and occur in suitable localities in great abundance; and, as they belong to the better class of fishes for the table, immense quantities are brought to the market. They spawn early in spring, and are in finest condition in the month of May. Individuals of seven or eight pounds weight are considered fish of large size, but specimens of double that weight have been caught. Plaice grow quickly and are tenacious of life; and, as they thrive in brackish water, their culture in littoral back-waters would seem to be deserving of every attention.

PLAINFIELD, a city of the United States, in Union county, New Jersey, lies at the foot of Mount Orange, and on the left side of the Green Brook, a tributary of the Raritan. It may to some extent be regarded as a residential suburb of New York, from which it is distant 24 miles by the Central Railroad. The local manufactures—hats and clothing—are comparatively trifling. Laid out in 1735 and made a city in 1869, Plainfield had 5095 inhabitants in 1870 and 8125 in 1880. A railroad consisting of narrow iron bands nailed down to wooden logs was constructed between Plainfield and Elizabeth as early as 1838. Two miles to the south-west is Washington's Rock, a coign of vantage from which the general used to watch the British movements.

PLAIN SONG, or **PLAIN CHANT** (*Gregorian Music*; Lat. *Cantus planus*; Ital. *Canto Gregoriano*; Fr. *Plain Chant*), a style of music, easily recognizable by certain strongly-marked characteristics, some very ancient fragments of which are believed to have been in use under the Jewish dispensation from a remote period, and to have been thence transferred to the ritual of the Christian church.

The theories advanced as to the origin of this solemn form of ecclesiastical music are innumerable. The most widely-spread opinion is that the older portion of it originated with the Psalms themselves, or at least sprang from the later synagogue music. Another theory traces the origin of plain song to the early Greeks; and the supporters of this view lay much stress on the fact that the scales in which its melodies are composed are named after the old Greek "modes." But, beyond the name,

³ Those in square brackets [] have not been seen by the writer.

no connexion whatever exists between the two tonalities, which bear not the remotest resemblance to each other. Less reasonable hypotheses attribute the origin of plain song to the Phœnicians, to the Egyptians, to the early Christian converts, and to the musicians of the Middle Ages. These divergent views, however, though entirely hypothetical, are defended by arguments so voluminous that for the elucidation of the subject we must content ourselves with referring the reader to the works of Gerbert, P. Martini, P. Kircher, Mersennus, P. Lambillotte, the Abbé Raillard, Coussemaker, Kiesewetter, Jakob, Ambros, and other authors, who have treated it at great length.

The earliest important fact upon which we can rest with absolute confidence is that towards the close of the 4th century Ambrose of Milan, fearing the loss or corruption of the venerable melodies which up to that time had been preserved to the church by means of oral tradition only, endeavoured to restore them as nearly as possible to their primitive purity, and at the same time to teach the clergy to sing them with greater precision than had previously been attempted. A still more extensive work of the same nature was undertaken, two centuries later, by Pope Gregory the Great. And thus arose two schools of ecclesiastical music, still known as the "Ambrosian" and the "Gregorian chant,"—the first of which is now practised only in the diocese of Milan, while the latter is universally accepted as the authorized "Roman use." In order to explain the essential differences existing between these two schools, we must here describe in detail some of the peculiar characteristics of plain song to which allusion has been made.

The melodies which collectively form the *repertoire* of plain chant are not written in modern major and minor scales, but in certain tonalities bearing names analogous to those of the early Greek "modes," though constructed on very different principles. Of these "modes," fourteen exist in theory, though twelve only are in practical use. The intervals of each "mode" are derived from a fundamental sound, called its "final."¹ The compass of each mode comprises eight sounds,—that of the first, third, fifth, seventh, ninth, eleventh, and thirteenth "modes," extending to the octave above the "final," and that of the second, fourth, sixth, eighth, tenth, twelfth, and fourteenth, extending from the fourth note below the final to the fifth note above it. Consequently, the "finals" of the first series, called the "authentic modes," occupy the lowest place in each system of sounds, and those of the second series, called the "plagal modes," the middle place,—the same "final" being common to one "authentic" and one "plagal mode." The following table exhibits the entire system, expressed in the alphabetical notation peculiar to modern English music,—the "final" being indicated in each case by an asterisk, and the position of the semitones, from which each mode derives its distinctive character, by brackets.

Authentic Modes.

1. Dorian, *D, E, F, G, A, B, C, D.
3. Phrygian, *E, F, G, A, B, C, D, E.
5. Lydian, *F, G, A, B, C, D, E, F.
7. Mixolydian, *G, A, B, C, D, E, F, G.
9. Æolian, *A, B, C, D, E, F, G, A.
11. Locrian, *B, C, D, E, F, G, A, B.
13. Ionian, *C, D, E, F, G, A, B, C.

Plagal Modes.

2. Hypodorian, A, B, C, *D, E, F, G, A.
4. Hypophrygian, B, C, D, *E, F, G, A, B.
6. Hypolydian, C, D, E, *F, G, A, B, C.
8. Hypomixolydian, D, E, F, *G, A, B, C, D.
10. Hypoæolian, E, F, G, *A, B, C, D, E.
12. Hypolocrian, F, G, A, *B, C, D, E, F.
14. Hypoionian, G, A, B, *C, D, E, F, G.

Nos. 11 and 12 in this series are rejected, for technical reasons into which we have not space to enter; they are practically useless.²

Of these modes Ambrose used four only—the first four

"authentic modes," now numbered 1, 3, 5, and 7. Gregory acknowledged, and is said by some historians of credit to have invented, the first four "plagal modes,"—Nos 2, 4, 6, and 8. The use of the remaining "modes," except perhaps the ninth, was not formally authorized until the reign of Charlemagne, who published an official decision upon the subject. In one or other of the twelve "modes" recognized by this decision, every plain-chant melody is composed. The number of such melodies preserved to us the genuineness of which is undoubted is immensely large; and the collection is divided into several distinct classes, the most important of which are the melodies proper to the *Psalm-Tones* and *Antiphons*; the *Ordinarium Missæ*, the *Introits*, *Graduals*, and *Offertoria*; the *Præfationes*, *Versiculi*, and *Responsoria*; the *Hymns* and *Sequences*; and the *Lamentationes*, *Exultet*, and other music used in Holy Week.

Of these classes the most interesting by far is that which includes the psalm-tones, or psalm-tunes, called by modern English historians, the "Gregorian tones." The oldest of these are tones 1, 3, 5, and 7, as sung by Ambrose. The antiquity of tones 2, 4, 6, and 8 is less firmly established, though there is no doubt that Gregory the Great sanctioned their use on strong traditional evidence. In addition to these, a peculiarly beautiful melody in mode 9, known as the *Tonus peregrinus*, has been sung from time immemorial only to the psalm *In exitu Israel*. The oldest version of this melody now extant is undoubtedly to a certain extent impure; but tradition imputes to it a very high antiquity, and even our doubts as to the authenticity of the now generally accepted reading extend only to one single note. A widely-accepted tradition points out this melody as the tune sung to *In exitu Israel*, as part of the Great Hallel (see PSALMS), which is generally (but hardly rightly) identified with the hymn sung by our Lord and His apostles immediately after the institution of the Last Supper.

One very powerful argument in favour of the Jewish origin of the psalm-tones lies in the peculiarity of their construction. We are not aware that this argument has ever been previously brought forward; but it is impossible to subject the venerable melodies to minute examination without observing their perfect adaptation to the laws of Hebrew poetry, as opposed to those which governed Greek and Latin verse. The division of the tune in every case, without exception, into two distinct strains, exactly balancing each other, points assuredly to the intention of singing it to the two contrasted phrases which, inseparable from the constitution of a Hebrew verse, find no place in any later form of poetry. And it is very remarkable that this constructional peculiarity was never imitated, either in the earliest hymns or antiphons we possess or in those of the Middle Ages,—evidently because it was found impossible to adapt it to any mediæval form of verse—even to the *Te Deum*, which, though a manifest reproduction of the Hebrew psalm, was adapted by Ambrose to a melody of very different formation, and naturally so since so many of its phrases consist of a single clause only, balanced in the following verse. This peculiarity now passes for the most part unnoticed; and the *Te Deum* is constantly sung to a psalm-tone, very much to the detriment of both. But in the Middle Ages this abuse was unknown; and so it came to pass that, until the "School of the Restoration" gave birth, in England, to the single chant, avowedly built upon the lines of its Gregorian predecessor, and a somewhat later period to the double one, so constructed as to weld two verses of the psalm into one, often with utter disregard to the sense of the words, the venerable psalm-tones stood quite alone—the only melodies in existence to which the psalms could

¹ Analogous to the tonic or key-note of the modern scale.

² For fuller information on the subject see the article "Modes, the Ecclesiastical," in Sir G. Grove's *Dictionary of Music*.

be chanted. And so intimate is the adaptation of these plain-chant melodies to the rhythm as well as to the sense of the sacred text, even after its translation into more modern languages, so strongly do they swing with the one and emphasize the other, that it is difficult to believe that the composition of the music was not coeval with that of the poetry.

Next in antiquity to the psalm-tones are the melodies adapted to the antiphons, the offertoria, the gradualls, and the introits, sung at high mass. Those proper to the *Ordinarium Missæ* are probably of later date. Those belonging to hymns and sequences are of all ages. Among the latest we possess—perhaps the very latest of any great importance—is that of *Lauda Sion*,—a very fine one, in modes 7 and 8, adapted to the celebrated sequence written by Thomas Aquinas about 1261.

To the melodies adapted to the *Lamentationes* and the *Exultet*, as sung in the Church of Rome during Holy Week, it is absolutely impossible to assign any date at all. All we know is that they are of extreme antiquity, and beautiful beyond all description. The melody of *Exultet* is, indeed, very frequently cited as the finest example of plain song in existence.

To assert that melodies so old as these have been handed down to us in their original purity would be absurd. But the presence of corruption rarely passes undetected by the initiated; and vigorous efforts have been made from time to time to purify the received text by reference to the oldest and most trustworthy MSS. attainable. Such an effort was made on a very extensive scale by the "Congregation of Rites," at the instigation of Pope Pius IX., in the year 1868; and the labours of that learned body, still in active progress, are doing all that can now be done towards the restoration of plain chant to the highest state of purity possible in the present stage of its existence.

(w. s. r.)

PLANARIANS. The name *Planaria* was first applied by O. F. Müller in his *Prodromus Zoologiæ Danicæ* (1776) to a group of worms, inhabitants of fresh and salt water, characterized, so far as was then known, by a flattened leaf-like form. Ehrenberg in 1831 changed this name to *Turbellaria* on account of the cilia with which the body is furnished, by means of which the worms create a whirlpool in the surrounding water. The extent of this group was subsequently more restricted, and at present the name *Turbellaria* is applied to all those (mainly free-swimming) Platyhelminths whose body is clothed externally with a ciliated epidermis (fig. 9), and which possess a mouth and (with the exception of one division) an alimentary canal, but are without an anus. The Turbellarians, excluding the NEMERTINES (*q.v.*), which until recently were classed with them, form an order of the class *Platyhelminthes*, and the old name *Planaria* is now confined to a group of the fresh-water representatives of this order.

Size and External Characters.—Many forms of the Turbellarians are so minute as to be hardly visible with the naked eye, while others attain to a length of several inches, and a land Planarian of no less than 9 inches in length has been described by Moseley. The freshwater forms are generally small, the largest representatives of the order being marine or terrestrial. The smaller species are mostly cylindrical, or convex dorsally and flat ventrally; the anterior extremity is commonly truncated and the posterior extremity pointed (fig. 1, *a, b*). The larger aquatic forms are thinner in proportion to the increasing surface of the body, so that they come to resemble thin leaf-like lamellæ (*d*), while the large land Planarians instead of increasing in superficies grow in length (*e* and *f*), so that they may be best compared to leeches. The larger aquatic forms are frequently provided

with tentacles in the shape of paired finger-like processes or ear-like folds of the anterior part of the body (*d* and *g*); sometimes the tentacles are papillary outgrowths of the dorsal surface; the

land Planarians are often to be distinguished by a crescent-shaped area at the fore end of the body, which is separated off from the rest (*f*). In many cases the whole dorsal surface is beset with papillæ (*d*). The aperture of the mouth varies greatly in its position; sometimes it is situated at the anterior extremity, sometimes in the middle of the ventral surface of the body, occasionally quite close to the posterior extremity; the single common or distinct male and female generative apertures are also situated upon the ventral surface of the body, and the former in rare cases open in common with the mouth; the genital apertures always lie behind the mouth. Many Turbellarians have a sucker which serves to attach the animal to surrounding objects, or to another individual during copulation.

Integument.—The integument is composed of a single layer of ciliated epithelium; between the cilia there are often long flagella and stiff tactile hairs and even (in a single instance) chitinous spines; these latter must be regarded as local thickenings of the firm cuticle which covers the epidermic cells. The epidermic cells are flat or columnar, and are united to each other by smooth opposed margins or by denticulate processes which fit into similar processes in the adjacent cells (fig. 2). Sometimes the epidermic cells are separated by an interstitial nucleated tissue. The structure and functions of the cells of the epidermis differ, and four varieties are to be found:—(*a*) indifferent ciliated cells; (*b*) cells containing certain definite structures (rhabdites, nematocysts); (*c*) gland cells; and (*d*) glutinous cells (Klebzellen). The rhabdites are refracting homogeneous rod-like bodies, of a firm consistency, which are met with in most Turbellaria, and often fill all the cells of the epidermis; they are not always found entirely within the cells, but the extremity often projects freely on to the exterior of the body. They are readily extruded from the cells by pressure, and are often found in great abundance in the mucus secreted by the glandular cells (many Turbellarians, like snails, deposit threads of mucus along their track); in this case the epidermic cells become perforated like a sieve. In many Turbellarians the rhabdites are chiefly massed in the anterior part of the body; frequently there are several varieties of rhabdites in one and the same species,—some being pointed at both ends, others cylindrical with truncated extremities. These structures are either formed directly in the ordinary epidermis cells as a kind of secreted product of the cell, or in special formative cells which lie beneath the integument and are connected with the epidermis cells by protoplasmic filaments, by means of which the rhabdites reach the surface of the body. These cells must be regarded as epidermic.

FIG. 1.—*a*, *Convoluta paradoxa*, Oe.; *b*, *Vortex viridis*, M. Sch.; *c*, *Monetus fuscus*, Gff.; *d*, *Thysanozoon brocchi*, Gr., with elevated anterior extremity (after Joh. Schmidt); *e*, *Rhynchodemus terrestris*, O. F. Müller (after Kennel); *f*, *Bipallium ceras*, Mos. (after Moseley); *g*, *Polycelis cornuta*, O. Sch., attached by the pharynx (*ph*) to a dead worm (after Johnson). All the figures of natural size, and viewed from the dorsal surface.

cells which have become disconnected with the epidermis itself, and wandered into the subjacent parenchyma. The function of the rhabdites seems to be to support the tactile sense. In rare instances nematocysts are present which in structure and development entirely resemble those of the *Ctenophora* (see vol. xii. p. 550). Very commonly structures known as pseudo-rhabdites are present; these have a rod-like form, but instead of being homogeneous are finely granular; they are an intermediate step between the rhabdites proper and a granulated secretion occasionally thrown off by the gland cells. The unicellular glands are either situated among the epidermic cells or in the parenchyma, in which case they are connected with the exterior only by the excretory duct. A peculiar modification of the epidermic cells are the so-called "glutinous cells," which occur on the ventral surface or at the hinder end of the body of many Turbellarians, and compensate for the suckers; the surface of these cells is furnished with numerous minute processes by means of which and a sticky secretion the animals can attach themselves to surrounding objects. Sometimes the epidermic cells contain calcareous concretions, and very commonly pigment is found either in the cells themselves or within the interstitial tissue. The colours of Turbellarians are, however, not always due to the pigment of the epidermis but to pigment contained in the parenchyma. Beneath the epidermis is a basement membrane (fig. 2, *bm*) which is in

FIG. 2.—Integument of *Mesostoma lingua*, O. Sch. On the right hand is the epidermis (*e*) with perforations (*p*) through which the rhabdites (*st*) project. Beneath this the basement membrane (*bm*), and beneath this again the muscular layers consisting of circular (*rm*), diagonal (*sm*), and longitudinal (*lm*) fibres.

some cases very delicate and structureless, and in other cases much thicker and enclosing branched cells; this membrane is attached more firmly to the subjacent tissue than to the epidermis. Since this tissue is the strongest in the body, and serves as a surface of attachment for the muscles, it has been termed by Lang a skeletal membrane.

The third section of the integument is formed by the muscular layers. These form a continuous covering to the rest of the body, but their arrangement and thickness are very different in different forms. In the smaller species (*Rhabdocelida*) there are two layers, an outer circular and an inner longitudinal, only in a few cases the circular layer is external to the longitudinal; sometimes there are three distinct layers, as in fig 2, where a diagonal layer is interposed. The larger forms (*Dendrocelida*) have a much more complicated muscular system: in the most differentiated forms there are six separate layers (two circular, two diagonal, and two longitudinal), which are, however, always less developed upon the dorsal than upon the ventral surface in that the thickest layer of the ventral surface (the innermost longitudinal) is absent or very feebly developed upon the dorsal side. Besides the

integumentary muscular system, there are also found dorso-ventral muscular bands which traverse the whole body from the dorsal to the ventral basement membrane, being branched at both extremities, and the special muscles of the pharynx, genital organs, and suckers.

The perivisceral cavity, bounded by the integument and traversed by the dorso-ventral muscles, contains the organs of the body—alimentary canal, excretory system, nervous system, and genital glands. The space left between these organs is filled with parenchyma; the latter varies much in appearance and is very difficult to study. Generally it consists of a network of fibres and trabeculae, which contain nuclei, and between which is a system of cavities filled during life with the perivisceral fluid. These cavities are generally but few in number and vary with the stronger or feebler development of the reticulum; they occasionally contain free cells.

Alimentary Canal.—All Turbellarians are furnished with a mouth, which, as there is no anus, serves both to take in nutriment and expel the undigested remains of food. The alimentary canal consists of a muscular pharynx and an intestine. The pharynx (figs 3, 5 to 8, *ph*) is cylindrical in form, rather complicated in structure, and surrounded by a muscular sheath, which opens on to the exterior by the mouth (*m*). Often the pharynx consists merely of a circular fold lying within the pharyngeal pouch (fig. 8); it can be protruded through the mouth and acts like a sucker, so that the animal can fasten itself upon its prey and draw it into the intestine by suction. At the junction of the pharynx with the intestine open the salivary glands, which are frequently large and well-developed (fig. 5, *s*). The intestine (*i*) has a very characteristic form in the different sections, and has long served to divide the *Turbellaria* into two groups:—(1) *Rhabdocelida*, with a straight unbranched intestine (figs. 5, 6), and (2) *Dendrocelida*, with a branched intestine (figs. 7, 8). In the latter group Lang has recently called attention to further differences that exist in the form of the intestine: in the *Tricladida* (fig. 7) there is no central "stomach," but three equally-sized intestinal branches (which have secondary ramifications) unite together to open into the pharynx; in the second group, the *Polycladida* (fig. 8), there is a median stomach (*st*), from which numerous intestinal branches arise; this stomach communicates directly with the pharynx; the branches of the intestine are much ramified and often form an anastomosing network. The epithelium of the intestine is a single layer of cells generally not ciliated, capable of protruding amoeboid processes by which the food is absorbed; the digestion of these animals is intracellular. Sometimes a muscular coat surrounds the intestine, the lumen of which is thus capable of being totally or partially contracted. To the above-mentioned divisions of the group, distinguished from each other by the varying form of the alimentary tract, another has been added, viz., the *Acœla* (Ulianin), which are characterized by the entire absence of any intestine. In these forms (fig. 4) the mouth leads directly into the parenchyma of the body by a short tube which is merely an invagination of the integument; the parenchyma is a syncytium, consisting of a soft protoplasmic mass with scattered nuclei, which represents the elements of the intestine and the body parenchyma (ento- and mesoderm) completely fused and without any traces of differentiation. This fact, as well as the disappearance of a nervous and excretory system, reduces the *Acœla* to the lowest position not only among the *Turbellaria*, but among the whole group of the *Vermes*.

Excretory System.—The excretory system of the Turbellarians is quite similar to that of the Trematodes and Cestoids; it consists of (1) the main trunks with their

external aperture, (2) the secondary branches of these, and (3) the excretory cells with the fine tubules leading from them. Rarely is there but a single main excretory trunk present opening at the hinder end of the body (*Stenostoma*); generally there are a pair of such trunks which open in common at the hinder end of the body, or separately (most *Rhabdocela*), or by the mouth (fig. 3).

In the *Tricladida* there are two or four lateral trunks present which open by a number of pores arranged in pairs upon the dorsal surface of the body; the same appears to be the case in the *Polycladida*. The main trunks of the excretory system are generally much twisted in their course, and anastomose with each other; they receive the fine tubules either directly or, as in the *Rhabdocela*, there is a network of secondary tubules interposed. The excretory cells are pear-shaped; they are branched and furnished with a nucleus and a large vacuole which is directly continuous with the lumen of the tubule; from the boundary wall of the vacuole springs a single flagellum, which depends into the lumen of the tubule and is capable of active movement. Lang discovered in a marine form of the *Tricladida* (*Gunda*) similar vacuolated cells with a single flagellum among the epithelial cells of the intestine, and came to the conclusion that the excretory cells were on that account derived from the epithelium of the intestine. The movements of the excretory fluid towards the external pore are directed by this flagellum as well as by cilia developed upon the walls of the fine tubules; the motion of all these cilia is such as to drive the contents of the tubules towards the excretory pore. The main trunks of the excretory system are either sparsely (*Tricladida* according to Jijima) or completely (*Polycladida* according to Lang) lined with cilia.

Sense Organs.—These are represented by tactile organs,

Nervous System.—The central organ of the nervous system, the brain (*cn*), is a double ganglion at the anterior end of the body, and has been noticed in all the known forms with the exception of the *Acoela*. It is situated in front of or above the pharynx; in those species in which a process of the intestine extends beyond the region of the brain (cf. figs. 7 and 8 viewed from the ventral surface) it is placed below this. In such cases there is sometimes a commissure encircling the prolongations of the intestine. Each of the two ganglia gives off a strong longitudinal nerve cord (figs. 5–8, *ln*) from which arise branches going to the various organs of the body. The structure of the nervous system is somewhat different in the *Rhabdocela*, *Tricladida*, and *Polycladida*. In the first group (figs. 5, 6) the two longitudinal cords and their branches are the most feebly developed, and there is but rarely (*Mesostoma*, *Monotus*) a transverse commissure uniting the longitudinal cords. These cords are very large in the *Tricladida*, where the brain is to be regarded as a simple thickening of them; in this group there are numerous transverse commissures between the longitudinal nerve cords (fig. 7), and the nerves arising from them and passing to the periphery form a subcutaneous nerve plexus within the muscular coat. Lang has observed a similar nerve plexus in the *Polycladida*, the central nervous system of which differs from that of the *Tricladida* in that a number of stout nerve cords radiate outwards from the brain as well as the

auditory organs (otoliths), and eyes. The whole surface of the body is very sensitive and (e.g., in the *Polycladida*) contains cells which end in tufts of fine hairs, so that certain regions thus become specially sensitive and serve as tactile organs. The anterior pointed extremity of the body in the *Rhabdocœla* is characterized by an abundant development of rhabdites and tactile hairs, and thus becomes a special tactile organ; in other cases this region of the body is transformed into a conical tactile proboscis which can be retracted into a sheath (*Proboscida*). In the freshwater *Tricladida* the anterior margin of the head is richly innervated, and is beset with a special row of tactile cells which contain no rhabdites; in the terrestrial forms of the same family (*Bipalium*) Moseley has described a row of papillæ along the crescent-shaped anterior extremity which can be

scattered over the whole of the anterior margin of the body and upon the tentacles. The eyes are always situated beneath the integument within the parenchyma, sometimes directly upon the brain or connected with it by special optic nerves. In its simplest form the eye is a pigmented spot with or without a refractory lens-like body; the more complicated eyes consist of a pigmented sheath containing a number of refracting rods which are connected at their outer extremity with a series of retinal cells, one to each rod; the retinal cells are prolonged into a nerve thread running to the brain; the arrangement of the visual elements is therefore precisely the same as in the vertebrate eye. Of great interest is the fact that in the *Polycladida* the number of eyes increases with the growth of the animal, and Lang has shown that the eyes increase in number by actual division. On the other hand Carrière has discovered by experimenting with certain freshwater *Tricladida* that the compound eyes (those containing a number of rods) are formed by the coalescence of several simple eyes. Only a single eye is found in the *Monotida*, which has the form of a simple pigment spot in front of the otolith.

Auditory organs are found in the shape of vesicles filled with fluid and containing circular lenticular or spindle-shaped otoliths formed of carbonate of lime. Otolithic vesicles of this kind are found in many *Rhabdocœlida* (*Acœla*, *Monotida*, fig. 4, *ot*) embedded in a depression on the anterior surface of the brain. In the *Dendrocoelida* these organs are but rarely present.

As a sensory organ of unknown function must be mentioned the paired lateral ciliated grooves which are met with on either side of the brain in many *Rhabdocœla* (fig. 9, *c*); they are also found commonly in NEMERTINES (*q. v.*), but are here more complicated in structure.

Reproductive Organs.—With a few exceptions all the Turbellarians are hermaphrodite, and reproduce themselves sexually. Only among the *Microstomida* is there an asexual as well as a sexual reproduction. The male and female organs open to the exterior, either through a common cloaca (*atrium genitale*) on the ventral surface (most *Rhabdocœlida* and all *Tricladida*, figs. 4–7), or there are separate male and female apertures. In this case the male aperture is generally placed in front of the female aperture (some *Rhabdocœlida* and all *Polycladida*, fig. 8), but occasionally the positions are reversed (certain *Rhabdocœlida*). The genital glands display a primitive condition on being paired, though frequently the germarium (fig. 5, *g*) of the *Rhabdocœla*, and occasionally also the testis, is developed only upon one side of the body.

The structure of the female organs varies. In some cases there are simple ovaries (*ov* in figs. 4, 8) in which the ova originate and become fully mature without being furnished with the secretion of a second gland; in other cases there is a division into germarium (fig. 5–7, *g*) and yolk gland (*y*); the primordial ova or germs originate in the former, and absorb the products of the yolk gland in the atrium, where they become ready for fertilization. An intermediate condition is seen in those forms where there is but a simple gland present which produces germs in its upper portion and yolk in the lower portion. The ovaries are generally compact round or tubular glands (fig. 4); sometimes they are formed of a number of pear-shaped follicles (fig. 8); there is usually a simple or paired uterus (*u*) which retains the ova for some time before they are deposited; sometimes, however, the ova undergo their development within the uterus and are completely developed before expulsion; in some cases the egg-shell is detached within the uterus so that the young are produced alive.

In Turbellarians without a yolk gland the uterus is a simple widening of the oviduct (fig. 8); in those forms which possess additional yolk glands the uterus is a simple or paired diverticulum of the atrium genitale (figs. 5, 7). The ova are either surrounded by a more or less hard chitinous shell, or one shell contains a number of ova ("cocoon" of *Tricladida* and many *Polycladida*). The *Polycladida* deposit an egg-string which like that of the *Gastropoda* consists of a number of eggs bound together by a transparent albumen-like mass. Many *Rhabdocœl* Turbellarians (e.g., *Mesostoma ehrenbergii*) produce two sorts of ova, thin-shelled summer ova and thick-shelled winter ova; the latter are capable of withstanding a considerable amount of desiccation, and are deposited in the autumn. The accessory female organs of reproduction are represented by bursæ seminales, which receive the semen during copulation and retain it

FIG. 8.—Plan of a Polycladid. *cn*, brain; *i*, intestinal branches; *i*₁, anterior unpaired intestinal branch; *ln*, longitudinal nerve cord; *m*, mouth; *od*, oviduct; *ov*, ovarian follicle; *ph*, pharynx; *ph*₁, pharyngeal pouch; *st*, stomach; *t*, testicular follicle; *u*, uterus; *v*, vas deferens; ♂, male copulatory organ, with the male aperture behind; ♀, female copulatory organ, with the female aperture before it. The eyes are omitted.

extended and form tactile organs; between the papillæ are peculiar ciliated grooves connected with nerves. In the *Polycladida* there are tactile cells with stiff hair-like processes on the summit of the dorsal papillæ and the various tentacular structures; the tentacles in this family also serve to support the eyes.

The majority of the Turbellarians possess eyes; the *Rhabdocœlida* commonly have two or four, as also have the *Tricladida*; the latter, however, are in some instances furnished with a greater number arranged in a continuous row round the anterior end of the body; in the *Polycladida* there are from fourteen to several hundred eyes arranged in two symmetrical groups round the brain or

until fertilization is accomplished. A further division of labour is brought about by the presence of two diverticula of the atrium genitale, one of which serves as a bursa copulatrix (fig. 5, *bc*) and the other as a receptaculum seminis (*rs*) in the same sense as the equivalent organs of insects. In the place of a special receptaculum seminis the efferent duct of the ovary is often (*Mesostomida*) metamorphosed into a chamber to contain the semen. In the *Tricladida* and *Polycladida* the female efferent duct is often differentiated into a muscular vagina which closely resembles the penis (figs. 7, 8, ♀).

Finally, the female generative apparatus is furnished with a number of glands which have been termed cement glands, albuminiferous glands, and shell glands.

The male sexual glands (figs. 4-8, *t*) resemble the ovaries in being either compact tubular (fig. 5) or follicular (figs. 4, 6, 7, 8) structures. The vasa deferentia (*vd*) are often widened out into vesiculæ seminales (figs. 4, 6, *vs*); or there are special vesiculæ seminales present, formed by a portion of the penis (fig. 5, *vs*). In the male organ of copulation there is frequently found in addition to the spermatozoa an accessory granulated secretion produced by special glands, but of unknown function.

The muscular penis, especially in the *Rhabdocela*, has a number of chitinous spines and hooks which serve to assist the animal in maintaining a firm hold during copulation, but also in capturing and retaining its prey. In *Macrorhynchus helgolandicus*, Giff., there is a peculiar poison dart connected with the male copulatory organ which only serves the latter purpose. Very remarkable is the opening of the penis into the mouth cavity in *Stylostomum* (*Polycladida*) and *Prorhynchus* (*Rhabdocela*), and also the existence of several (2-15) pairs of male copulatory organs and genital apertures in certain *Polycladida*.

The spermatozoa vary much in form, especially in the *Rhabdocalida*, where frequently the species of one and the same genus are distinguished by the different form of the spermatozoa. Copulation in the Turbellarians is generally reciprocal; only in those cases where both summer and winter ova (see above) are formed do the former arise from self-fertilization; the latter are the result of the copulation of two individuals. The fertilization of the ova always takes place in the atrium genitale. Many Turbellarians, especially the *Acela*, display the phenomenon known as "successive hermaphroditism," the male organs of an individual attain to maturity first, and the female organs become ripe subsequently. During copulation, therefore, one individual is physiologically a male and the other a female.

Asexual generation is met with only in the *Microstomida*; it takes the form of transverse division accompanied by budding. The posterior third of the body becomes separated off by a septum running from the gut to the integument and an external furrow corresponding to this; this part of the body grows in length until it equals the anterior portion. By further repetition of this double procedure of separation and equalization there, chains of 4, then 8, 16, and 32 buds are formed, which remain attached (fig. 9), and, although fresh mouth apertures (*m'*, *m''*, *m'''*) have been formed, are still in communication by the intestinal lumen; this becomes closed before or after the several buds break off from their connexion with each other. Throughout the whole summer chains of zooids are met with; in autumn this asexual division probably ceases to occur; the several individuals become sexually mature, separate from each other, and lay eggs which remain quiescent during the winter and in the spring develop into fresh individuals reproducing asexually.

Development.—The study of the development of the Turbellarians is unfortunately not very far advanced, particularly among the small *Rhabdocalida*, which are extremely difficult to investigate, and about which hardly any developmental facts are known. The larger freshwater *Tricladida* and the *Polycladida* on the contrary have been recently very fully investigated. The *Rhabdocela* and the *Tricladida* appear to develop directly without any metamorphosis, while a great part of the *Polycladida* undergo a metamorphosis and pass through a larval condition, during which they are furnished with provisional ciliated processes (fig. 10); the *Acela* have also a free larval form; pelagic larvae with a coat of long cilia apparently belonging to this group have been observed by Ulianin. The segmentation of the ovum is total, but unequal; an epibolic gastrula is formed and the aperture of invagination becomes the permanent mouth of the adult.

Systematic Arrangement and Mode of Life.—Order Turbellaria.—Platyhelminths with a ciliated integument, a mouth and pharynx, but no anus; with paired cerebral ganglia and two lateral nerve cords; sexual organs hermaphrodite; chiefly free-swimming.

Sub-order A. *Rhabdocalida*.—Of small size; body cylindrical or depressed; without an intestine, or with a simple unbranched intestine; the female genital glands always compact, not follicular; genital apertures single or distinct.

Tribe I. *Acela* (fig. 1, *a*).—With a digestive parenchyma not differentiated into intestine and parenchyma proper; with no nervous system or excretory organs; sexual organs hermaphrodite, with follicular testes and paired ovaries; generally without a

pharynx, but having otoliths; all the forms marine. Many quite flat, with the lateral margins bent down towards the ventral surface (*Convoluta*), frequently with brown or green parasitic algae in the parenchyma.

Tribe II. *Rhabdocela* (fig. 1, *b*).—Intestinal tract and parenchyma separate; nervous system and excretory organs present; with compact testes and female generative glands (ovaries or separated germarium and yolk glands); with a complicated pharynx, but generally without otoliths. Numerous forms, freshwater and marine; the genus *Prorhynchus* (two species) also in damp earth. The *Microstomida* (fig. 9) propagate asexually.

Fig. 9.

Fig. 9.—*Microstoma lineare*, Oe., undergoing division. There are 16 individuals, 8 with mouth apertures, showing the buds of the first (*m*), second (*m'*), third (*m''*), and fourth (*m'''*) generation. The fifth generation has not yet acquired a mouth aperture. *c*, ciliated grooves; *e*, eye spots; *i*, intestine.

Fig. 10.

Fig. 10.—Larva of *Yungia aurantica*, L. (*Polycladida*), with provisional ciliated processes (after A. Lang).

Freshwater forms mostly belong to the families *Mesostomida* and *Vorticida*, some of which contain green parasitic algae. Marine forms include representatives of these two families and of the *Proboscida* (with a tactile proboscis). Of the family *Vorticida*, the genera *Graffia* and *Anopliodum* are parasitic, the former in Gastropods the latter in Echinoderms (Holothurians).

Tribe III. *Alloicocela* (fig. 1, *c*).—Intestinal tract and parenchyma separate; nervous system and excretory organs present; with follicular testes and compact female glands (as in the *Rhabdocela*); pharynx similarly developed as a shorter or longer sac. One family (*Monotida*), with otoliths. All the species marine, with one exception, *Plagiostoma lemani*, which lives in the deep water of the Alpine lakes.

Sub-order B. *Dendrocoelida*.—Large forms, with a flattened body, branched intestine, follicular testes and follicular yolk glands or ovaries; without otoliths.

Tribe I. *Tricladida*.—Body elongate; intestine with three main branches uniting to open into a cylindrical retractile pharynx; with follicular testes, two round germariums, and numerous yolk follicles, with a single sexual aperture. *Planaria*, *Dendrocoelum*, *Polyelis* (fig. 1, *g*) are inhabitants of fresh water (with great power of reproduction). Terrestrial forms (fig. 1, *e*, *f*) of leech-like shape, especially met with in the tropics (only two European species *Rhynchodemus terrestris* and *Geodesmus bilineatus*); marine forms *Gunda* (characterized by a metameric structure), *Bdelloura* (external parasite of *Limulus*).

Tribe II. *Polycladida* (fig. 1, *d*).—Body leaf-like, thin, and broad, with numerous branched or retiform intestinal caeca which unite to form a central tube (stomach); with follicular testes and follicular ovaries, with two separated genital apertures, the male in front of the female; without (*Acotylea*) or with (*Cotylea*) a sucker situated behind the female generative opening. All marine.

Literature.—The most recent works, which also contain a full account of what has gone before, are the following:—*Rhabdocela*.—L. v. Graff, *Monographie der Turbellarien*: I. *Rhabdocalida*, Leipzig, 1882, with 20 plates. *Marine and Freshwater Tricladida*.—A. Lang, "Der Bau von *Gunda segmentata* und die Verwandtschaft der Platyhelminthen mit Cölenteraten und Hirudineen," in *Mitth. Zool. Stat. Neapel*, vol. iii., 1881; El. Metschnikoff, "Die Embryologie von *Planaria polychroa*," in *Zeitschr. f. wiss. Zool.*, vol. xxxviii., 1883; Isao Jijima, "Untersuchungen über den Bau und die Entwicklungsgeschichte der Süßwasser-Dendrocoelen," in *Zeitschr. f. wiss. Zool.*, vol. xl., 1884. *Land Planarians*.—

PLANCK, GOTTLIEB JAKOB (1751-1833), theologian and church historian, was born at Nürtingen in Württemberg, where his father was a notary, on November 15, 1751. He was educated for the Protestant ministry at Blaubeuren, Bebenhausen, and Tübingen, and from 1774 to 1784 held successive appointments as repetent, preacher, and professor in Tübingen and Stuttgart. In 1781 he published anonymously the first volume of his *Geschichte des Protestantischen Lehrbegriffs*; the second, also anonymous, appeared in 1783; and in 1784 he was chosen to succeed Walch at Göttingen. Here in the course of a long and useful professional career he enjoyed a large number of academical and ecclesiastical honours. His death took place on August 31, 1833.

The *Geschichte des Protestantischen Lehrbegriffs* was completed in 6 vols. in 1800. It was followed by an extensive *Geschichte der Kirchenverfassung*, in 5 vols. (1803-1809). Both are works of considerable importance, and are characterized by abundant learning and acuteness, the most conspicuous fault in the eyes of his least favourable critics being a tendency, which cannot be wholly denied, to "subjective pragmatism."

PLANTAGENET. This surname, distinctive of a line of kings who ruled in England for more than three hundred years, was first adopted by Geoffrey, count of Anjou, in reference to a sprig of broom (*planta genistæ*) which he is said to have worn in his bonnet. He is described by early writers as a very handsome man, but there was certainly nothing very striking in his character. He was the son of Fulk, count of Anjou, king of Jerusalem, who, before his departure for the Holy Land, placed him in possession of the counties of Anjou and Maine. This made him in the eyes of Henry I. of England, who was anxious to protect Normandy, an eligible husband for his widowed daughter, the empress Maud, whom he proposed to make his heiress, both in England and beyond sea. It was a purely political marriage, and the couple immediately afterwards had violent quarrels. Nor was either of them popular in England, where a female sovereign would at that time have been an innovation, and Geoffrey was disliked as a foreigner—although the same objection might have seemed to apply to Stephen of Blois, whose superior activity gained possession of the throne before Maud could make good her pretensions. In a long war with the usurper, though recognized as "lady of England" and virtual sovereign by one part of the country, she was only able in the end to secure the succession for her son. Stephen ended his days in peace, and the house of Plantagenet succeeded to the throne in the person of Henry II. by virtue of a compact.

Henry, the son of Geoffrey of Anjou and the empress Maud, was born at Le Mans in the year 1133, and was just twenty-one years of age when he attained the crown. But his youth had been well spent in preparation for it. When eight years old he was brought to England to be trained in arms. At sixteen he was knighted by his great-uncle David of Scotland. In 1151 his father put him in possession of Normandy, and, dying soon after, left him also the succession to Anjou. These advantages he improved next year by his marriage with Eleanor of Aquitaine, which, by adding Poitou and Guienne to his dominions, gave him the lordship over the whole western side of France from north to south, with the exception of Brittany, which also some time afterwards came under his power.

Having thus, even before he was twenty, become master of so many fair provinces, he then sailed to England, and, though he did not dethrone Stephen, compelled him to acknowledge him as his successor. Next year he was king. It is a new era in the history of England as well as in the fortunes of his house. The country, which was lately so impatient of the rule of a foreigner—fearing, doubtless, that English interests would be sacrificed to those of Anjou—now yields an easy submission to the ruler of all western France from Picardy to the Pyrenees. And, though Henry is in fact one of the greatest of Continental potentates, greater really than his feudal superior the king of France, there is no great cause for anxiety. Henry devotes himself to the interests of his island kingdom, takes steps to secure the succession there to his issue, causing his eldest son even to be crowned king during his own lifetime, and is much more intent on the subjugation of Wales and Ireland and the recognition of his feudal superiority over Scotland than upon any extension of his responsibilities abroad. Personally a man of fiery temperament and strong passions, his patience as a politician is remarkable. Bit by bit he is building up a strong empire, and even keeping the pretensions of the church within definite and reasonable bounds. But a single angry word undoes the work of years. He is responsible for Becket's murder. He must do penance and make his peace with the church. He must humiliate himself before Becket's grave.

His dynastic policy seemed almost an equal failure, but was productive of wide and far-reaching consequences. His ungrateful sons rebelled against him, and when he heard that even John had joined the confederacy he felt that he had nothing more to live for. The eldest, Henry, whom he had been so anxious to make a king during his own life, sickened and died in France after flagrant acts of ingratitude and impiety. Geoffrey, to whom he had secured the duchy of Brittany, soon followed his brother; and there remained but Richard and John, besides three daughters, who were all disposed of in marriage to Continental princes. As Richard, though he came to the crown, also died without legitimate issue, the male line was continued in the two sons of John, Henry III. and Richard, king of the Romans, and the issue of the latter became extinct in the next generation.

It is remarkable how the prosperity of England seemed to keep pace with the stability of the succession. The short reigns of Richard I. and John were times of peculiar misery, which was only brought to a climax by the war of the Great Charter and by the dauphin being called in to enforce it. Matters improved under Henry III., even during the minority; but he, too, had a war with his barons in the latter part of his reign. He, too, like his father, had but two sons who grew up to manhood; and, while the elder, Edward I., succeeded him on the throne and was the ancestor of all the following kings, the younger, Edmund Crouchback, became progenitor of the house of Lancaster by the marriage of his great granddaughter Blanche to John of Gaunt, fourth son of Edward III. Edward I. had three sons who came to man's estate; Edward II. only two, or more properly only one, for the second, John of Eltham, died in Scotland at the age of nineteen. Finally the time of Edward III. with his great family was the climax in the fortunes of the house of Plantagenet. Nor need we pursue the family history further, as the story of its descent after the days of Edward III. will be found sufficiently treated elsewhere (see LANCASTER, HOUSE OF, and YORK, HOUSE OF).

Of the alliances of this great dynasty the most important after the days of Henry II. were those of the house of Lancaster. Henry III. married his daughter Margaret to Alexander III. of Scotland, and another daughter to the

duke of Brittany. Edward I. had for his sons-in-law Gilbert de Clare, earl of Gloucester, the duke of Brabant, and the earl of Holland. A daughter of Edward II. married a duke of Gueldres. But "the aspiring blood of Lancaster" spread itself over Europe by alliances with Castile and Portugal, Navarre and Denmark, Bavaria and other foreign states. It has reigned in Portugal to the present day, and it continued to reign in Spain till the end of the 17th century. (J. GA.)

PLANTAIN (Lat. *plantago*), a name given to plants with broad palm-like leaves. This is the case with certain species of *Plantago*, *Alisma*, and *Musa*, to all of which the term is popularly applied. Of the *Plantago* little need be said here, the species being for the most part mere weeds, though one species, *P. lanceolata*, is eaten by cattle, and the seeds of another, *P. major*, are collected for the food of birds. Of far greater general importance is the genus *Musa*, to which belong the Plantain, and the BANANA (q.v.). These are gigantic herbs, now diffused by cultivation throughout the tropics of both hemispheres, and

sending up from a short thick underground stem shoots with a number of very large leaves whose long, thick leaf-stalks are wrapped one round another. The blades are usually oblong-obtuse, like the blade of an oar, with a very thick midrib from which diverge on each side numerous parallel densely arranged secondary ribs. The flowers are borne in huge pendulous spikes provided with large boat-shaped, often coloured, bracts, in whose axils the whorls of flowers are produced; the lower ones

Musa sapientum.

are usually female or hermaphrodite, those at the apex of the spike are male only. These flowers consist of a perianth of six divisions partly united below, slightly two-lipped above, and enclosing five perfect and one imperfect stamen. The ovary is inferior and three-celled—ripening into a long oblong fruit filled with spongy pulp, in which the numerous seeds are embedded. The accumulation of starch and sugar in this pulp renders the fruit of vast importance as an article of diet in the tropics. Corenwinder, cited by Pavy, says that, while starchy matter forms more than 19 per cent. of the ripe fruit—there is also nearly 5 per cent. of nitrogenous matter, about double that of the potato. The plant requires but little attention, and the produce from a relatively small area is enormous; hence it is one of the most valuable of all food-plants. After fruiting, the stem dies down, but provision for new growth is made by the production from the underground stock of numerous offsets. The number of varieties is very great, a circumstance which in itself testifies to the long period during which the plant has been cultivated. It is also the more remarkable in that perfect seeds are comparatively rarely produced, the inference being that the different forms have arisen from bud-variations or "sports." In spite of the vast number of varieties grown in the tropics of both hemispheres—varieties mostly dependent on diversities in the size, form, and flavour of the fruit—the general opinion among botanists is that they have all sprung from one species, the *Musa sapientum* of Brown. Were it otherwise, it is presumed that the varieties found in

America would be different from the Asiatic ones, and these again from those found in the South Sea Islands, &c.; but, as a matter of fact, there are no geographic limitations, the same varieties being found in different quarters of the globe. The varieties are arranged under two heads by Desvaux according to the size of their fruit—the bananas, with fruit 7–15 inches in length, and the fig bananas, with fruit from 1–6 inches long; but these variations are not constant, and Schomburgk has recorded a case in which a spike of the fig banana bore numerous fruits proper to that variety, and in addition a large number of fruits like those of the Chinese dwarf-plantain, *Musa chinensis*, the Cavendish banana of gardens—a case analogous to, but even more remarkable than, the not infrequent occurrence of peaches and nectarines on the same branch. The plantain and the banana are sometimes spoken of as distinct. The former has a green stem and yellow angular fruit not fit for eating till cooked. The banana (*M. sapientum*) has the stem marked with purple spots, and a shorter more cylindric fruit which may be eaten without cooking, but the two run one into the other so that no absolute distinction can be drawn between them. The species have been found in a wild state in Chittagong and Khasia, in the Philippine Islands, in Siam, and in Ceylon, but nowhere truly wild on the American continent.

Throughout tropical and subtropical Asia the plant has numerous and diverse native names; and it was mentioned by old Greek and Latin authors. On the other hand, there are no native names for the plant in Mexico, Peru, or Brazil. From such considerations as these Alphonse de Candolle, in his *Origine des Plantes Cultivées*, sums up the evidence by asserting the Asiatic origin of the plantain and its early introduction into America by the Spaniards or Portuguese. If it should turn out that the banana or the plantain existed in America before the discovery of that continent, then M. de Candolle would attribute that circumstance to some fortuitous introduction at no very remote date rather than to the simultaneous existence of the banana as an indigenous plant in both hemispheres.

It is not only for their fruit that these plants are valuable. The leaves are used for thatching, and the abundant fibre they contain forms a good substitute for hemp. *Musa textilis* is of special value from this point of view. The Abyssinian banana, *M. Ensete*, has dry capsular fruit, and very handsome foliage.

PLANTAIN-EATER. See TOURAKOO.

PLANTIN, CHRISTOPHE (1514–1589), born in a village near Tours (probably Saint-Avertin) in 1514, learned book-binding and book-selling at Caen, and, having married in that town, settled in 1549 as bookbinder in Antwerp, then the principal commercial town of the Netherlands, where he was soon known as the first in his profession. A bad wound in the arm, which unfitted him for this occupation, seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was *La Institutione di una fanciulla nata nobilmente*, by J. M. Bruto, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an heretical pamphlet, which caused his movables to be seized and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business on a larger scale. Among them were two grand-nephews of Dan. Bomberg, who furnished him with the fine Hebrew types

of that renowned Venetian printer. He was now in a position to spare no expense in printing his books with all the care he deemed necessary; and his editions of the Bible in Hebrew, Latin, and Dutch, his *Corpus Juris*, Latin and Greek classics, and many other works produced at this period are renowned for their beautiful execution and accuracy. A much greater enterprise was planned by him in those years—the publication of a *Biblia Polyglotta*, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II. king of Spain, who sent him the learned Benedictus Arias Montanus to take the leading part in the work of editorship. With his zealous help the work was finished in five years (1569–73, 8 vols. fol.). Plantin earned much renown by it, but little profit, or rather less than none; but in compensation he received the privilege of printing all liturgical books for the states of King Philip, and the office of “prototypographus regius,” which carried with it the oversight over all printers in the Netherlands, a charge of which Plantin seems to have acquitted himself indifferently. This need not surprise us, when we know that Plantin, though outwardly a faithful son of the church, was till his death the partisan of a mystical sect of heretics; and it is now proved that many of their books published without the name of a printer came from his presses together with the missals, breviaries, &c., for the Roman Catholic Church.

Besides the polyglott Bible, Plantin published in those years many other works of note, such as editions of St Augustine and St Jerome, the botanical works of Dodonæus, Clusius, and Lobelius, the description of the Netherlands by Guicciardini, &c. In 1575 his printing-office reckoned more than twenty presses and seventy-three workmen, besides a similar number that worked for the office at home. But soon there came bad times for Antwerp. In November 1576 the town was plundered and in part burnt by the Spaniards, and Plantin had to pay an exorbitant ransom. A great many inhabitants of the once flourishing city emigrated, and Plantin also thought of settling elsewhere. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leyden, and invited him to occupy this place, he left his much reduced business in Antwerp to his son-in-law John Moerentorf (Moretus) and Francis van Ravelinghen (Raphelengius), and settled at Leyden. But he could not thrive, it seems, in Holland. When in 1585 Antwerp was taken by the prince of Parma and affairs became there more settled, he left the office in Leyden to Raphelengius and returned to Antwerp, excusing himself for having served the states of the revolted provinces by the difficulties of his situation. In Antwerp he laboured till his death on the 1st July 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note “in officina Plantiniana,” but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left all the old things in the office untouched, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 francs, the authorities were able with little trouble to create one of the most remarkable museums in existence (Musée Plantin, opened 19th August 1877).

See Max Rooses, *Christophe Plantin imprimeur Anversois*, Antwerp, 1882; Aug. de Backer and Ch. Euelens, *Annales de l'imprimerie Plantinienne*, Brussels, 1865; Degeorge, *La maison Plantin*, 2d ed., Brussels, 1878. (P. A. T.)

PLANTING. See ARBORICULTURE.

PLASENCIA, a city of Spain and an episcopal see, in the north of the province of Caceres (Estremadura), is

pleasantly situated on the right bank of the Xerte or Jerte, a sub-tributary of the Tagus, and at the foot of the sierras of Bejar and Vera, continuations of the Guadarrama range. Industrially and commercially insignificant, the place has some interest for the artist and ecclesiologist on account of its fine walls, built in 1197 by Alphonso VIII. of Castile, and of its cathedral, begun in 1498, which is a favourable specimen of the ornate Gothic of its period, and also shows good examples of the workmanship of Berruguete, Aleman, and other artists. The population of the ayuntamiento was 7090 in 1877. The Hieronymite convent of Yuste, the scene of the last years of the emperor Charles V., lies about 24 miles to the eastward, and is most conveniently reached from Plasencia.

PLASTER OF PARIS. See GYPSUM.

PLATA, LA. See ARGENTINE REPUBLIC.

PLATA, RIO DE LA. See PLATE RIVER, p. 187.

PLATÆA, or PLATÆA, a celebrated city of ancient Greece, lay at the foot of the northern slope of Mount Cithæron in Boeotia, about $6\frac{1}{2}$ miles by road south of Thebes, or a little over 5 geographical miles in a direct line. Its territory was separated from that of Thebes by the river Asopus. The Thebans claimed to have founded Plataea, but, however this may have been, Plataea was always at feud with its more powerful neighbour. In 519 B.C. the Plateans, being hard pressed by Thebes, applied for help to the Spartan king Cleomenes, who advised them to place themselves under the protection of Athens. They did so, and Athens and Plataea were thenceforward fast friends. It was perhaps on this occasion that the Plateans were granted that restricted citizenship of Athens which we know that they enjoyed at a later time. When Athens faced the Persians alone at Marathon, the Plateans to a man marched out to their help and shared in the victory (490 B.C.). From that day the names of Athens and Plataea were always associated in solemn prayers at Athens. Though dwellers in an inland town, and therefore ignorant of seamanship, the Plateans helped to man the Athenian ships at the sea fight with the Persians off Artemisium (480). In revenge the Persians burned Plataea. The great battle of Plataea, which finally secured the freedom of Greece against the Persians, was fought on the uneven and broken ground to the east and north of the town (September 479). After the battle the Greeks declared the city and territory of Plataea to be independent and inviolable. The Plateans undertook to bring annual offerings of food and raiment to the graves of those who had fallen in the battle; and a festival of liberation (Eleutheria) was celebrated every fifth year. These offerings continued to be brought, and the festival to be held, as late as the 2d century of our era. With the spoils of the Persian wars the Plateans raised a temple of Athene the Warlike.¹ The Peloponnesian War began with an attempt of the Thebans to seize Plataea (431 B.C.). The attempt failed, but in 427, after a siege of about two years, the city was taken by the Peloponnesians and the garrison put to the sword. The bulk of the population had previously taken refuge in Athens. A year afterwards the Thebans razed the city to the ground, and built a large hospice close to the old temple of Hera, to whom they erected a new temple 100 feet long. In 421 the surviving Plateans received from the Athenians the town of Scione in Macedonia as a residence, but they had no doubt to quit it at the end of the war (404). When the peace of Antalcidas was concluded between Greece and Persia (387) Plataea was restored, but a few years afterwards it was surprised and destroyed, except the temples, by the Thebans (about 373). The Plateans were again received

¹ It was built, according to Plutarch (*Arist.* 20), after the battle of Plataea; according to Pausanias (ix. 4, 1), after the battle of Marathon.

at Athens, where they were now admitted to full citizenship, except that they were not eligible for the priesthood and the archonship. After the battle of Chæronea (338) Philip of Macedon brought back the Plataeans as a counterpoise to the power of Thebes, but the walls were not fully restored till some years later. Alexander the Great, then monarch of Asia, contributed to rebuild them, in recognition, he declared, of the services which the Plataeans had rendered against the Persians of old. With the loss of Greek freedom Plataea sank into insignificance. The inhabitants lived on the glories of the past, and were regarded as braggarts by the rest of the Boeotians. In the 6th century the walls were once more restored by Justinian.

The fullest description of ancient Plataea is that of Pausanias, who visited it in the 2d century. The great temple of Hera, he tells us, contained a statue of Rhea by Praxiteles; the temple of Athene the Warlike was adorned with an image of the goddess by Phidias and paintings by Polygnotus. Close to the city gates were the tombs of the Greeks who had fallen in the battle of Plataea, and an altar and image of Zeus the Liberator in white marble. The ruins of the ancient town lie about 500 yards east of the modern village of Kokhla. They occupy a slightly elevated plateau forming a rude triangle about two and a half miles in circumference, of which the apex to the south almost touches the great rocky slope of Cithæron, and the base to the north has a steep though short descent to the plain. The outer walls follow the edge of the plateau, but an inner cross-wall divides it into two unequal parts. The southern and higher part is probably as old as the Persian wars; the masonry of the northern part is more recent, and probably belongs to the age of Philip and Alexander. It is likely that these two parts were never included at the same time within the city walls, but that the southern was the ancient city, and that at one of the restorations (perhaps that of 387 B.C.) the northern and more spacious part of the plateau was preferred as the site. Within this northern half, and close to the northern wall, is a terrace on which may have stood the temple of Hera. The north-western corner of the northern town is portioned off by a wall, and is conjectured to have been the acropolis of the newer city.

See Dodwell's *Tour through Greece*, i. p. 274 sq.; Leake's *Travels in Northern Greece*, vol. II. chap. 16; and Bursian's *Geographie von Griechenland*, vol. I. p. 243 sq.

PLATE. The word *plate* (connected with the Greek *πλατῆς*, flat, the late Latin *plata* = *lamina*, and the Spanish *plata*, silver) is usually employed to denote works in silver or gold which belong to any class other than those of personal ornaments or coins.¹

On account of the ease with which it can be worked and the pure state in which it is generally found, it is probable that gold was the first metal used by man; and it is certain that, in some countries at least, he attained to the most marvellous skill in its manipulation at a time when the other arts were in a very elementary condition. As an instance of this we may mention a sword of the bronze age, found in a barrow near Stonehenge, and now in the museum at Devizes.² The hilt of this sword is covered with the most microscopically minute gold mosaic. A simple design is formed by fixing tesserae, or rather pins, of red and yellow gold into the wooden core of the handle. Incredible as it may appear, there are more than two thousand of these gold tesserae to the square inch. The use of silver appears to belong to a rather later period, probably because, though a widely spread metal in almost all parts of the world, it is usually found in a less pure state than gold, and requires some skill to smelt and refine it. Though both these precious metals were largely and skilfully used by prehistoric races, they were generally employed as personal ornaments or decorations for weapons. Except in Scandinavian countries but little that can be called "plate" has been discovered in the early barrows of the prehistoric period in western Europe.

¹ In mediæval English the term "a plate" was occasionally used in the sense of a silver vessel. A curious survival of this use of the word still exists at Queen's College, Oxford, where the servants may yet be heard asking at the buttery for so many "plates of beer," that is, silver tankards.

² Hoare, *Ancient Wiltshire*, 1840.

It will be convenient to consider the no less prehistoric gold and silver work recently found at Troy, Tiryns, and Mycenæ as forming a stage in the history of Greek art.

Ancient Egypt.—An enormous amount of the precious metals was annually brought as tribute to the Egyptian kings; according to Diodorus, who quotes the authority of Hecataeus, the yearly produce of the royal gold and silver mines amounted to thirty-two millions of minæ—that is, about 133 millions sterling of modern money. Though this estimate is probably an exaggeration, the amount must have been very great. The gold chiefly came from the mines in the Bishâri desert, about eighteen days' journey south-east of Kum Ombos. These mines were constantly worked down to the time of the Arab caliphs, but now appear to be exhausted. It is not known where the silver came from. Gold appears to have been relatively more abundant than silver, and the difference in value between them was very much less than it is now. Tribute was paid to the Egyptian kings, not in coined money, which was then unknown, but in rings or ingots. Owing to the Egyptian practice of burying with their dead personal ornaments and jewellery, rather than other possessions less intimately connected with the person of the deceased, but few specimens of either gold or silver plate have survived to our times, whereas the amount of gold jewellery that has been discovered is very large, and shows the utmost amount of skill in working the precious metals. We can, however, form some notion of what the larger works, such as plates and vases in gold and silver, were like from the frequent representations of them in mural sculpture and paintings. In many cases they were extremely elaborate and fanciful in shape, formed with the bodies or heads of griffins, horses, and other animals real or imaginary. Others are simple and graceful in outline, enriched with delicate surface ornament of leaves, wave and guilloché patterns, hieroglyphs, or sacred animals. Fig. 1 shows a gold vase of the time of Thothmes III. (Dynasty XVIII., about 1500 B.C.), taken from a wall-painting in one of the tombs at Thebes. The figure on its side is the hieroglyph for "gold." Others appear to have been very large and massive, with human figures in silver or gold supporting a great bowl or crater of the same metal.

FIG. 1.—Gold Vase, from wall-paintings at Thebes.

In the language of the hieroglyphs silver is called "white gold," and gold is the generic name for money,—unlike most languages, in which silver usually has this special meaning,—a fact which points strongly to the priority of the use of gold. On the walls of one of the tombs at Beni Hassan there is an interesting representation of a gold- and silver-smith's workshop, showing the various processes employed—weighing, melting or soldering with the blow-pipe, refining the metal, and polishing the almost finished bowl or vase. In the time of Rameses III., about 1300 B.C., a clearly defined Assyrian influence appears in the decoration of some of the gold plate. A gold basket, represented in the tomb of this king at Thebes, has on its side a relief of the sacred tree between two beasts, the oldest of purely Aryan or Indo-European subjects, and quite foreign to Egypt.

The chief existing specimens of Egyptian plate are five silver *phiale* or bowls, found at the ancient Thumuis in the Delta, and now in the Bulak Museum (Nos. 482 to 486 in the catalogue). These are modelled in the form of a lotus blossom, most graceful in design, but are apparently not earlier than the 5th century B.C. The Louvre possesses a fine gold patera, 6½ inches across, with figures of fishes

within a lotus border in repoussé work; an inscription on the rim shows it to have belonged to an officer of Thothmes III. (*Mém. Soc. Ant. de France*, xxiv. 1858).

Assyrian and Phœnician Plate.—Among the many treasures of early art found by General Cesnola in the tombs of Cyprus none are of more interest than a large number of Phœnician silver phialæ or saucer-like dishes, enriched with delicate repoussé and tooled reliefs, which in their design present many characteristics of Assyrian art mingled with a more or less strong Egyptian influence. A considerable number of bowls and phialæ found in Assyria itself are so exactly similar to these Cyprian ones, both in shape and ornamentation, that they cannot but be classed together as the production of the same people and the same age. The British Museum possesses a fine collection of these bowls, mostly found in the palace at Nimrud. Though they are made of bronze, and only occasionally ornamented with a few silver studs, they are evidently the production of artists who were accustomed to work in the precious metals, some of them in fact being almost identical in form and design with the silver phialæ found at Curium and elsewhere in Cyprus. They are ornamented in a very delicate and minute manner, partly by incised lines, and partly by the repoussé process, finally completed by chasing. Their designs consist of a central geometrical pattern, with one or more concentric bands round it of figures of gods and men, with various animals and plants. In these bands there is a strange admixture of Assyrian and Egyptian style. The main motives belong to the former class, the principal groups being purely Assyrian—such as the sacred tree between the two attendant beasts, or the king engaged in combat and vanquishing a lion single-handed; while mingled with these are figures and groups purely Egyptian in style, such as the hawk-headed deity, or a king slaying a whole crowd of captives at one blow. Fig. 2 gives a silver dish from

The Curium find alone is said to have included more than a thousand objects in gold and silver.

Etruscan Plate.—The Etruscan races of Italy were specially renowned for their skill in working all the metals, and above all in their gold work. Large quantities of the most exquisite gold jewellery have been found in Etruscan tombs, including, in addition to smaller objects, sceptres, wreaths of olive, and massive head-pieces. The Museo Kircheriano in Rome possesses a magnificent specimen of the last form of ornament; it is covered with nearly a hundred little statuettes of lions arranged in parallel rows.¹ Little, however, that can be classed under the head of plate has yet been found. A number of silver bowls found in Etruscan tombs have ornaments in the Egypto-Assyrian style, and were probably imported into Italy by the Phœnicians; some almost exactly resemble those found in Cyprus.

The British Museum (gold ornament room) possesses a fine specimen of early plate found at Agrigentum in Sicily. This is a gold phiale or bowl, about 5 inches

FIG. 3.—Archaic Gold Phiale, found at Agrigentum, now in the British Museum. It is shown in section below. It is 5 inches in diameter.

across, with central boss or omphalos (φιάλη μεσόμφαλος) which seems once to have contained a large jewel. Round the inside of the bowl are six figures of oxen, repoussé in relief, and at one side a crescent, formed by punched dots. A delicate twisted moulding surrounds the edge; the workmanship of the whole is very skilful (see fig. 3).

Hellenic Plate.—Discoveries made of late years on the plains of Troy, at Mycenæ, and at Camirus in Rhodes have brought to light a large quantity of gold and silver plate of very remote antiquity. These early specimens of plate are all very similar in character, graceful in shape, hammered, cast, and soldered with great skill, but, with the exception of weapons and ornaments, mostly devoid of surface decoration. The most remarkable find was that which Dr Schliemann calls "Priam's treasure," including a large number of silver vases and bowls, with fine massive double-handled cups in gold, and a very curious spherical gold bottle. Fig. 4 shows a silver cup, with gold mounts, found in a tomb at Camirus in Rhodes, apparently a work of the same early date and class. Homer's poems are full of descriptions of rich works in both the precious metals (*Iliad* xxiii. 741), showing that the taste for valuable pieces of plate was developed among the Greeks at a very early time—much more so probably than it was during

¹ Another, very similar, exists in the Vatican Mus. Gregor.

FIG. 2.—Silver Bowl, about 7 inches in diameter, found in a tomb in Cyprus, with repoussé reliefs of Egyptian and Assyrian style

Curium containing examples of all the above mentioned subjects. Some of the designs are exceedingly beautiful, and are arranged with great decorative skill: a favourite composition is that of antelopes walking in a forest of tall papyrus plants, arranged in radiating lines, so as to suit the circular phiale, and yet treated with perfect grace and freedom. In addition to the numerous silver phialæ some were found, with similar decoration, made of pure gold.

the most flourishing period of Hellenic art, when the production of beautifully painted fictile vases seems to some extent to have superseded the more barbaric magnificence

FIG. 4.—Silver Cantharus from Rhodes, with gold mounts. Possibly the form of the Homeric *δέπας ἀμφικύπελλον*.

of gold and silver. During the 6th century B.C. the demand for works of this class, valuable not only for their material but for their workmanship, seems to have been very great under the last dynasty of Lydian kings, whose wealth in gold and silver has become proverbial. Croesus especially encouraged the art, and paid enormous sums for silver vases and cups to the most renowned artists of his time, such as Glaucus and Theodorus the Samian.

Pliny (*N. H.*, xxxiii.) gives a valuable account of the sources whence the Greeks and Romans derived their precious metals, their methods of refining, and the sculptors who were most celebrated for their skill in making articles of plate. Among the Greeks and Romans the greatest artists of the day did not disdain to practise this branch of art. The same sculptor who produced noble and colossal statues for the temples of the gods would at another time put forth his utmost skill and artistic talent in chasing and embossing some small silver cup or vase. In this way ancient pieces of plate ranked among the most perfect productions of art—very different from the custom of the 19th century, which leaves its plate to be executed by some dull mechanical craftsman, after the pompous designs supplied by a tradesman whose only standard of merit appears to be the pretentiousness of the design and the number of ounces of silver it contains.

In the best times of Greek art, the chief works in gold and silver seem to have been dedicated to religious purposes, and to have been seldom used for the ostentatious pomp of private individuals. Vessels for the use of the temples, tripods in gold or silver of the richest work, and statues of the gods were the chief objects on which the precious metals were lavished.¹

The gold used by the Greeks probably came from Asia Minor or Egypt, while the mines of Laurium, in the mountains which form the promontory of Sunium in Attica, supplied an abundant amount of silver for many centuries.² According to Pliny, Phidias was the first sculptor who produced works of great merit in the precious metals; he mentions a number of other Greek artists who were celebrated for this class of work, but unluckily does not give their dates. The chief of these were Mentor and Mys (both of the 5th century B.C.), Acragas, Boethus, the sculptors Myron and Stratoniceus, as well as the well-known Praxiteles and Scopas. In Pliny's time many works in gold and silver by these artists still existed in Rhodes and elsewhere. Among later workers he specially mentions Zopyrus, who made two silver cups, embossed with the scene of the judgment of Orestes by the Areopagite court, and Pytheas, who made a bowl with reliefs of Ulysses and Diomedes carrying off the Palladium. Enormous prices were given by wealthy Romans for ancient silver plate made by distinguished Greek artists; according to Pliny, more than £300 an ounce was paid for the last-mentioned cup.

Though a large quantity of later Græco-Roman plate still exists in various museums, the specimens of Greek silver-work of the best period are extremely rare, and mostly unimportant in point of size. In 1812 Dr Lee discovered at Ithaca a very beautiful vase or cyathus $3\frac{3}{4}$ inches high (see fig. 5) and a phiale or patera, $9\frac{1}{2}$ inches

FIG. 5.—Silver Crater, found in Ithaca. $3\frac{3}{4}$ inches high.

across, both of silver, repoussé and chased, with very rich and graceful patterns of leaves and flowers—suggesting a slight tinge of Assyrian style.³ These are probably not later than the 5th century B.C. A good many silver mirror-cases, with repoussé figure-subjects in high relief, have been found at various places; as, for instance, one with a beautiful seated figure of Aphrodite found at Tarentum and now in the British Museum.⁴ The South Kensington Museum contains a most exquisite little silver vase found in the baths of Apollo at Vicarello in Italy (fig. 6), enriched with a band in low relief of storks devouring serpents, executed with gem-like minuteness and finish—probably not later than the 3rd century B.C. The British Museum has a little vase of similar form and almost equal beauty, though perhaps later in date; it is decorated with bands of vine branches in a graceful flowing pattern, and is partly gilt. The most important find of Greek silver plate, mingled with pieces of Roman or Græco-Roman work, was that discovered in the crypt of the temple of Mercury Augustus, at Villeret, near Bernay, in France (the ancient Canetum), in 1830.⁵ It

¹ The gold eagles on the sacred omphalos at Delphi were notable examples of this; see Pindar, *Pyth.* iv. 4.

² Boeckh, *Silver Mines of Laurium*, 1842.

consists of silver vessels and two silver statuettes, sixty-nine pieces in all, the gift of various donors to the temple. It is in itself a small museum of specimens of ancient plate, containing objects of great variety of date and workmanship, from fine Greek work of about 300 B.C. down to the coarser Roman production of the 2nd or 3rd century A.D. The shapes of the vessels composing this treasure are very numerous—ewers, bowls, pateræ, large ladle-shaped cups, and drinking cups with and without handles. Those of Greek workmanship are in slight relief, while some of the Roman wine-cups and bowls have heads and figures almost detached from the ground. Some of these latter much resemble some silver canthari found in Pompeii.¹ The dedicatory Roman inscriptions, in some cases, appear to be later additions, made by the various donors who presented these treasures to the temple.² It is interesting to note that two vases among the Bernay treasure have reliefs of the theft of the Palladium, like the celebrated cup by Pytheas mentioned by Pliny; another subject described by him as decorating silver plate by Zopyrus, the judgment of Orestes, is represented on a fine cup found at Antium, apparently of Greek design, which is preserved in the Corsini Palace in Rome. These may possibly be copies from originals by those much-renowned artists.

Græco-Roman and Roman Plate.—Of what may be called Græco-Roman plate a much larger number of specimens still exist. Even during the 1st century the growing pomp and ostentation of the wealthy Romans led to an enormous demand for large and elaborate pieces of plate, while their good taste induced them to prefer the works of Greek *celatores*,—a branch of art which even at that time showed but little signs of decay. It was no doubt the desire for objects which should combine intrinsic value with artistic merit, and also be of a more durable sort, that by slow degrees gave the death-blow to the art of vase painting. It is not always easy to distinguish the best works in silver of this Roman period from the more purely Greek works of an earlier time. They are often of the highest merit both in design and execution. The finest collection of these was found in 1869 at Hildesheim in Hanover, and is now in the Berlin Museum. They consist of a large number of cups, bowls, vases, dishes, and tripods, all of silver, some decorated with gilding and enriched in the most elaborate way with figure and scroll-work reliefs of the greatest beauty and finish; these, except one or two of very rude work, can hardly be later in date than the first century after Christ. The most remarkable is a cylix, inside which a geometrical Greek border in slight relief forms a frame for a seated figure of Athene—an “*emblema*” soldered on, in very high relief. The attitude of this figure, the folds of the drapery, and other details are arranged with extreme grace. Almost the only point which recalls the fact that this exquisite piece does not belong to the best period of Greek art is the very salient relief of the figure, whereas in earlier times the silver-worker was content with a more moderate amount of relief, and thus decorated the surface of his vessel without injuring its main contour. A large silver crater in the same set (fig. 7) is free from this fault. It is covered outside with delicate floral scroll-work, growing in graceful curves all over the surface of the vessel, with very slight projection from the main surface,—a perfect model in every way for the treatment of silver. Pliny specially mentions the custom of Roman generals and other officers travelling on military

expeditions with magnificent services of plate; and it appears probable that this had been the case with the

FIG. 7.—Silver Crater, 15½ inches high, from the Hildesheim find. (Berlin Museum.)

Hildesheim treasure; defeat or some other disaster may have forced the Roman owner to hide and relinquish the whole set.³

The museum at Naples contains a very large number of silver cups found in Pompeii, encrusted with figure-subjects or branches of ivy and vine in relief. In cases of this sort the cup is made double, with a smooth inner skin to hide the sinkings produced by the repoussé work in relief on the outside. Silver vessels ornamented in relief were called by the Romans *celata* or *aspera*, to distinguish them from plain ones, which were called *levia*.⁴

Among later specimens of Roman plate the most remarkable is the gold patera, nearly 10 inches in diameter, found at Rennes in 1777, and now in the Paris Bibliothèque—a work of the most marvellous delicacy and high finish—almost gem-like in its minuteness of detail. Though not earlier than about 210 A.D., a slight clumsiness in the proportion of its embossed figures is the only visible sign of decadence. The outer rim is set with sixteen fine gold coins—*aurei* of various members of the Antonine family from Hadrian to Geta. The central *emblema* or medallion represents the drinking contest between Bacchus and Hercules, and round this medallion is a band of repoussé figures showing the triumphal procession of Bacchus after winning the contest. He sits triumphant in his leopard-drawn car, while Hercules is led along, helplessly intoxicated, supported by bacchanals. A long line of nymphs, fauns, and satyrs complete the circular band.

The so-called “shield of Scipio,” also in the Paris Bibliothèque, which was found in the Rhone near Avignon, is the finest example of Roman plate of the 4th century. It is not a shield, but a large silver patera, about 26 inches in diameter, with a repoussé relief representing the restoration of Briseis to Achilles. The composition and general design are good, but the execution is feeble and rather coarse.

³ Darcel, *Trésor de Hildesheim*, 1870. The number of gold and silver statues in Rome was very great. In the inscription of Ancyra, Augustus records that he melted down no less than 80 silver statues of himself, and with the money thus obtained presented “golden gifts” to the temple of Apollo Palatinus. See *Mon. Ancyra.*, ed. Mommsen, 1883.

⁴ For the various classical methods of working in silver and gold see METAL-WORK.

¹ Quaranta, *Quattordici Vasi d'Argento . . . Pompei*, Naples, 1837.

² See a valuable paper on this subject in the *Journal of Hellenic Studies*, vol. iii. No. 1, by Dr Waldstein, who attributes part of this treasure to the Ephesian school of artists, and traces in some of the designs miniature reproductions of large works of Greek sculpture.

The British Museum possesses good specimens of Roman silver work in its last stage of decline. These are two large caskets or toilet boxes, with silver unguent vases, oblong *lances*, *pateræ*, ewers, spoons, and other objects, all found in Rome in 1793. The caskets are decorated in low relief with somewhat blunt repoussé figures and ornaments. The rim of one casket is incised with the following words—*SECUNDE ET PROIETA VIVATIS IN CHRISTO*. One of the silver vases has the words *PELEGRINA VTERE FELIX*. The legend on the casket, and the ✠ which appears among the ornaments, show that it was made for a Roman lady, named Projecta, who was a Christian; her portrait, together with that of her husband Secundus, is on the centre of the lid in a medallion supported by two cupids. With the exception of a pair of small silver two-handled vases, undecorated, but of the purest Greek-like form, these various pieces of silver work probably date from the 5th century.¹

Plate from the Crimea.—The finest collection of early gold and silver plate is that in the Musée de l'Ermitage at St Petersburg, the result of many years' excavation in the tombs of the Cimmerian Bosphorus.² Most of these magnificent pieces of plate, both in style of workmanship and the character of their decoration, resemble the work of Greek artists; in some cases nothing but the costume of the figures embossed upon them shows that they were not produced in Athens.

The earliest in style is a massive gold phiale (φιάλη μεσόμφαλος) covered with the richest and most minute surface ornament. The motive of the design is taken from an open lotus flower; the petals form radiating lobes, and these petals are entirely covered with delicate scroll-work, surrounding Greek-like gorgons' heads, and other smaller heads, savage-looking and bearded. Though perhaps rather overloaded with ornament, this beautiful phiale, which shows strong traces of Phœnician or Assyrian influence, is a real masterpiece of decorative design. Of later date, probably 4th century B.C., is a small gold bottle, Hellenic in form, but ornamented with a band of non-Hellenic figures in relief—Scythian bowmen, as their dress clearly shows. The grandest piece of all is a large silver amphora, of about the same date, shaped like the Greek fictile amphoræ, and ornamented with a beautiful flowing pattern, of pure Hellenic honeysuckle form, mingled with birds and very highly projecting animals' heads. On the shoulder of the vase there is a band of Scythians and horses, executed with great spirit and refinement.³ It is difficult to believe that this splendid vase, so graceful in outline, and so pure in its decoration, was not produced by some famous Athenian *toreutes*.

Oriental Plate.—Some very curious pieces of plate both in gold and silver have been found in northern India; these appear to be of native workmanship, but the subjects with which they are embossed, and the modelling of the figures, show that they were produced under late Roman influence, or in some cases possibly even Greek influence in a highly degraded state, handed down from the time of Alexander's Indian conquests.

Under the Sasanian kings of Persia (from the 3rd to 6th centuries) very massive and richly decorated gold vases, bowls, and bottles were made (fig. 8). Those which still exist show a curious mingling of ancient Assyrian art with that of Rome in its decline. Reliefs representing winged lions, or the sacred tree between its attendant beasts, alternate with subjects from Roman mythology,

such as the rape of Ganymede; but all are treated alike with much originality, and in a highly decorative manner. The Paris Bibliothèque and the Vienna Museum contain some fine specimens.

The gold and silver work of Russia resembles in style that of Byzantium at an early period. Shrines and other magnificent pieces of plate in the treasury of the cathedral at Moscow (see Weltmann, *Le trésor de Moscou*, 1861), though executed at the end of the 15th century, are exactly similar in design to Byzantine work of the 11th or 12th century, and even since then but little change or development of style has taken place.

The caliphs of Baghdad, the sultans of Egypt, and other Moslem rulers were once famed for their rich stores of plate, which was probably of extreme beauty both in design and workmanship. Little or nothing of this Moslem plate now remains, and it is only possible to judge of its style and magnificence from the fine works in brass and other less valuable metals which have survived to our time.

Early Mediæval Plate.—The Gothic, Gaulish, and other semi-barbarian peoples, who in the 6th century were

Fig. 8.

Fig. 9.

Fig. 8.—Sasanian Gold Bottle, about 10 inches high. In the Vienna Museum.
Fig. 9.—Gold Ewer, 15 inches high, from the Petrossa treasure.

masters of Spain, France, and parts of central Europe, produced great quantities of work in the precious metals, especially gold, often of great magnificence of design and not without some skill in workmanship. In 1837 a large number of pieces of very massive gold plate were found at Petrossa in Roumania; much of this find was unfortunately broken up and melted, but a considerable portion was saved, and is now in the museum at Bucharest. These magnificent objects are all of solid gold, and consist of large dishes, vases, ewers, baskets of open work, and personal ornaments (fig. 9). Some of them show a strong Roman influence in their design, others are more purely barbaric in style. To the first of these classes belongs a very fine phiale or patera, 10 inches in diameter. In the centre is a seated statuette of a goddess, holding a cup, while all round, in high relief, are standing figures of various male and female deities, purely Roman in style. Though the execution is somewhat clumsy, there is much reminiscence of classical grace in the attitudes and drapery of these figures. A large basket and other pieces, made of square bars of gold arranged so as to form an open pattern of stiff geometrical design, have nothing in common with the vessels in which Roman influence is

¹ Visconti, *Una Supellettile d'Argento*, Rome, 1825.

³ *Gaz. des B. Arts*, xxv. 19–39, 1882.

apparent, and can hardly be the work of the same school of goldsmiths.¹ The date of this Petrossa treasure is supposed to be the 6th century. The celebrated Gourdon gold cup and tray now preserved in Paris belong to about the same date. They are very rich and magnificent, quite free from any survival of classic influence, and in style resemble the Merovingian gold work which was found in the tomb of Childeric I. The cup is three inches high, shaped like a miniature two-handled chalice; its companion oblong tray or plate has a large cross in high relief in the centre. They are elaborately ornamented with inlaid work of turquoises and garnets, and delicate filigree patterns in gold, soldered on.

In the 6th century Byzantium was the chief centre for the production of large and magnificent works in the precious metals. The religious fervour and the great wealth of Justinian and his successors filled the churches of Byzantium, not only with enormous quantities of gold and silver chalices, shrines, and other smaller pieces of ecclesiastical plate, but even large altars, with tall pillared baldacchini over them, fonts, massive candelabra, statues, and high screens, all made of the precious metals. The wealth and artistic splendour with which St Peter's in Rome and St Sophia in Constantinople were enriched is now almost inconceivable. To read the mere inventories of these treasures dazzles the imagination,—such as that given in the *Liber Pontificalis* of Anastasius Bibliothecarius, which includes the long list of treasures given by Constantine to St Peter's before he transferred his seat of empire to Byzantium (330), and the scarcely less wonderful list of gold and silver plate presented to the same basilica by Pope Symmachus (498–514).²

During the 7th century France and other Western countries were but little behind Italy and Byzantium in their production of massive works, both secular and religious, in the precious metals. St Éloy, the French goldsmith bishop, made a number of most splendid shrines and other sacred furniture in beaten gold—among them large shrines for the relics of St Denis, St Geneviève, and St Martin, as well as gold thrones, plate, and jewellery for the French kings Clothaire II. and Dagobert I. At this time every cathedral or abbey church in Germany, France, and even England began to accumulate rich treasures of every kind in gold and silver, enriched with jewels and enamel; but few specimens, however, still exist of the work of this early period. The most notable are Charlemagne's regalia³ and other treasures at Aix-la-Chapelle, a few preserved at St Peter's in Rome, and the remarkable set of ecclesiastical utensils which still exist in the cathedral of Monza near Milan—the gift of Queen Theodelinda in the early part of the 7th century.⁴

The existing examples of magnificent early work in the precious metals mostly belong to a somewhat later period. The chief are the gold and silver altar in Sant' Ambrogio at Milan, of the 9th century; the "Pala d'Oro," or gold retable, in St Mark's at Venice, begun in the 10th century (see METAL-WORK); and the gold altar frontal given by the emperor Henry II. and his wife Cunigunde, at the beginning of the 11th century, to the cathedral at Basel. The last is about 4 feet high by 6 feet long, repoussé in high relief, with figures of Christ, the three archangels, and St Benedict, standing under an arcade of round arches; it is now in the Cluny Museum in Paris.⁵ A similar gold frontal, of equal splendour, was that made for the archbishop of Sens in 999. This was melted down by Louis

XV. in 1760, but fortunately a drawing of it was preserved, and is published by Du Sommerard (*Album*, 9th series, pl. xiii.).

A most valuable description of the various methods of work practised by gold- and silver-smiths in the 11th and 12th centuries is given by the monk Theophilus in his *Diversarum Artium Schedula* (Hendrie's ed., 1847). He minutely describes every possible process that could be employed in making and ornamenting elaborate pieces of ecclesiastical plate—such as smelting, refining, hammering, chasing and repoussé work, soldering, casting (by the "cire perdue" process), wire-drawing, gilding with mercury: amalgam, and the application of niello, enamel, and gems.

The silversmith of those days, as in classical times, was not only a thorough artist with a complete sense of beauty and fitness in his work, but he was also a craftsman of the most varied fertility of resource, and made himself thoroughly responsible for every part of his work and every stage through which it passed,—a most striking contrast to the modern subdivision of labour, and eagerness to produce a show of neatness without regard to real excellence of work, which is the curse of all 19th-century handicrafts, and one of the main reasons why our modern productions are in the main neither works of true art nor objects of real lasting utility.

Italian Plate.—Before the latter part of the 15th century, large pieces of silver work were made more for ecclesiastical use than for the gratification of private luxury. The great silver shrine in Orvieto cathedral, made to contain the blood-stained corporal of the famous Bolsena miracle, is one of the chief of these. It is a very large and elaborate work in solid silver, made to imitate the west front of a cathedral, and decorated in the most sumptuous way with figures cast and chased in relief, and a wonderful series of miniature-like pictures embossed in low relief and covered with translucent enamels of various brilliant colours. This splendid piece of silver work was executed about 1338 by Ugolino da Siena and his pupils. The other most important pieces of silver work in Italy are the frontal and retable of St James in the cathedral at Pistoia, and the altar of San Giovanni at Florence (see METAL-WORK). On these two works were employed a whole series of the chief Tuscan artists of the 14th and 15th centuries, many of whom, though of great reputation in other branches of art, such as painting, sculpture on a large scale, and architecture, did not disdain to devote their utmost skill, and years of labour, to work which we now as a rule consign to craftsmen of the very smallest capacity.

Among the distinguished names of Florentines who during the space of one century only, the 15th, worked in gold and silver, the following may be given to suggest the high rank which this class of work took among the arts:—Brunelleschi, Ghiberti, Donatello, Luca della Robbia, the two Pollaiuoli, Verrocchio, Michelozzo, Ghirlandaio, Botticelli, Lorenzo di Credi, Baccio Baldini, and Francia. The cities of Italy which chiefly excelled in this religious and beautiful class of silver-work during the 14th and 15th centuries were Florence, Siena, Arezzo, Pisa, and Pistoia.

Owing to the demoralization and increase of luxury which grew in Italy with such startling rapidity during the early years of the 16th century, the wealth and artistic skill which in the previous centuries had been mainly devoted to religious objects were diverted into a different channel, and became for the most part absorbed in the production of magnificent pieces of plate—vases, ewers, dishes, and the like—of large size, and decorated in the most lavish way with the fanciful and over-luxuriant forms of ornament introduced by the already declining taste of the Renaissance. This demand created a new school of metal-workers, among whom Benvenuto Cellini

(1500–1571) was perhaps the ablest, and certainly the most prominent. His graphic and often shameless autobiography makes him one of the foremost and most vivid figures of this wonderful 16th century, in which the most bestial self-indulgence was mingled with the keenest enthusiasm for art. Cellini's work is always perfect in execution, but very unequal in merit of design; some of his silver pieces, such as the large salt-cellar made for Francis I., are much marred by an attempt to produce a massive grandeur of effect, on a scale and in a material quite unsuited to such ambitious and sculpturesque effects. Cellini's influence on the design of silver plate was very great, not only in Italy and France, where his life was spent, but also on the great silversmiths of Augsburg and Nuremberg, many of whose finest pieces are often attributed to Cellini.¹ During the 17th and even the 18th centuries fine pieces of plate were produced in Italy, many of them still retaining some of the grace and refinement of the earlier Renaissance.

Germany.—From very early times Germany was specially famed for its works in the precious metals, mostly, as in other countries, for ecclesiastical use. In the 15th century a large quantity of secular plate was produced, of very beautiful design and the most skilful workmanship. Tall covered cups or hanaps on slender stems, modelled with a series of bosses something like a pineapple and surmounted by a cleverly wrought flower, or beakers, cylindrical tankards with lids, enriched with delicate Gothic cresting or applied foliage, are the most beautiful in form and decoration. On the lids of these cups are frequently placed heraldic figures, holding shields with the

FIG. 10.—Silver Beaker, decorated with open work, filled in with translucent enamels. German or Flemish, of the 15th century. (S. K. M.)

owner's arms, modelled and cast with great spirit and finish. One celebrated silver beaker, of about 1400, now in the South Kensington Museum (fig. 10), is ornamented with Gothic traceried windows filled in with translucent enamels.² Another,³ rather later in date, preserved in the print room of the British Museum, is covered with figures and foliage in minute niello work, a most elaborate and splendid piece of plate.

During the first half of the 16th century Augsburg and Nuremberg, long celebrated for their silver work, developed a school of artists in plate whose productions are of the most unrivalled beauty, at once graceful in general form and decorated in slight relief with arabesques, strap-work, wreaths, and figure subjects arranged with the utmost good taste, and modelled and chased with the most perfect precision of touch. Though influenced by the contemporary silver-work of Italy, the works of Paul Flint, Wenzel

Jamnitzer (1508–1585), and Theodor de Bry of Liège (1528–98) are free from the extravagance of outline and over-elaboration of detail which often disfigure the grand silver pieces of men like Cellini (see fig. 11). In Germany the traditions of earlier Gothic art were less rapidly broken with; and many purely Gothic forms survived there till quite the end of the 16th century. In the first half of the 17th century the technical skill of the German silversmiths reached its highest point of perfection, but there was some falling off in their designs, which rapidly lost their purity of outline. Switzerland produced several silversmiths whose work is similar to that of this German school, especially their large plateaux and ewers, most richly and gracefully covered with ornament, all finished with almost gem-like minuteness. The principal among these artists was François Briot, all of whose productions are of extreme beauty. The majority of his existing works are not in silver, but in pewter, and thus by their absence of intrinsic value have escaped the melting pot (fig. 12). Gaspar Enderlein was another workman of this school, whose productions cannot always be distinguished from those of Briot. Though born in Switzerland, these artists really belong to the great Augsburg and Nuremberg school.

Many of the famous 15th and 16th century painters, such as Martin Schön, Israel von Mecken, and Holbein, used to supply the silver-workers with elaborate designs for plate. Virgil Solis of Nuremberg (1514–1562) was especially fertile in this sort of invention, and executed a large series of etchings of designs for vases, cups, ewers, tazze, and all sorts of plate.⁴

Spain.—Throughout the Middle Ages Spain was remarkable for its large and magnificent works in the precious metals. The cathedral of Gerona still possesses a most massive silver retable, made by a Valencian silversmith called Peter Bernec. The gold and silver altar-

⁴ See twenty-one facsimiles of these rare etchings published by J. Rimell, London, 1862.

frontal, a work of the 11th century, was carried off from this cathedral by the French in the present century. Another very large and beautiful piece of silver work is the throne, Northern Gothic in style, made for King Martin of Aragon, about 1400, and now preserved in Barcelona cathedral. Till after 1500 little that is distinctively Spanish appears in the style of their silver work. At first Moorish influence, and then that of France and Germany, appear to have been paramount. It is not till the 16th century that a really Spanish school of art was developed; and the discovery of America with its rich stores of gold and silver gave an enormous impetus to this class of work.¹ The "custodia," or tabernacle for the host, in many of the Spanish cathedrals, is a large and massive object, decorated in a very gorgeous though somewhat debased style. In spite of the plundering of the French, even now no country is so rich in ecclesiastical plate as Spain.

England.—The Celtic races of both England and Ireland appear to have possessed great wealth in gold and silver, but especially the former. It seems, however, to have been mostly used in the manufacture of personal ornaments, such as torques, fibulæ, and the like. A magnificent suit of gold armour, repoussé with simple patterns of lines and dots, was found some years ago at Mold in Flintshire, and is now in the British Museum.² The amount of gold jewellery found in Ireland during the past century has been enormous; but, owing to the unfortunate law of "treasure-trove," by far the greater part was immediately melted down by the finders. Little of this period that can be called plate has been discovered in the British Isles,—unlike Denmark and other Scandinavian countries, where the excavation of tombs has in many cases yielded rich results in the way of massive cups, bowls, ladles, and horns of solid gold, mostly decorated with simple designs of spirals, concentric circles, or interlaced grotesques. Others are of silver, parcel-gilt, and some have figure subjects in low relief (fig. 13). In like

FIG. 13.—Silver Cup, 4½ inches high, with embossed gold band; found in a grave in the east of Seeland (Denmark). This cup dates from the earlier part of the Iron Age.

manner, during the Saxon period, though gold and silver jewellery was common, yet little plate appears to have been made, with the exception of shrines, altar-frontals, and vessels for ecclesiastical use, of which every important church in England must have possessed a magnificent stock. With regard to English secular plate, though but few early examples still exist, we know from various records, such as wills and inventories, that the 14th century was one in which every rich lord or burgher prided himself on his fine and massive collection of silver vessels; on festive occasions this was displayed, not only on the dinner-table, but also on sideboards, arranged with tiers of steps, one above the other, so as to show off to advantage the weighty silver vases, flagons, and dishes with which it was loaded. The central object on every rich man's table was the "nef"—a large silver casket, usually (as the name suggests) in the form of a ship, and arranged to contain the host's napkin, goblet, spoon, and knife, with an assortment of spices and salt. Great sums were often spent on this large and elaborate piece of plate, e.g., one made for the duke of Anjou in the 14th century weighed

348 marks of gold. The English silversmiths of this period were highly skilled in their art, and produced objects of great beauty both in design and workmanship. One of the finest specimens of late 14th century plate which still exists is a silver cup belonging to the mayor and corporation of King's Lynn. It is graceful and chalice-like in form, skilfully chased, and decorated in a very rich and elaborate way with coloured translucent enamels (fig. 14) of ladies and youths, several with hawks on their wrists.³ Silver salt-cellars were among the most elaborate pieces of plate produced

Fig. 14.

Fig. 15.

FIG. 14.—Silver Cup, with translucent enamels. Probably French work of the 14th century.

during the 15th century. Several colleges at Oxford and Cambridge still possess fine specimens of these (fig. 15); the favourite shape was a kind of hour-glass form richly ornamented with spiral fluting or bosses.

But few existing specimens of English plate are older than the beginning of the 15th century. Among the few that remain the principal are two or three chalices—such as the two large gold ones found in the coffin of an archbishop of York, now used for holy communion in the cathedral, and a fine silver chalice from the church of Berwick St James, Wilts, now in the British Museum. Both this and the York chalices are devoid of ornament, but, judging from their shape, appear to be of the 12th or 13th century.⁴

It is interesting to note the various changes of form through which the ecclesiastical chalice passed from early Christian times till the 16th century. It was at first an ordinary secular cup (fig. 16, A), with two handles classical in form, and of large capacity, because the laity as well as the clergy received the wine. The double handles were of practical use in passing the cup round like a modern "loving cup." The first alteration was the omission of the handles, so that it took the form B, with large hemispherical bowl, a round foot, and a knop for security in holding it. For some centuries it appears to have been the custom for the priest to hold the chalice, while the communicant sucked the wine through a silver tube or "fistula." Some of the most magnificent

³ See Carter, *Specimens of Ancient Sculpture*, &c., 1838.

⁴ Among the most important existing specimens are the solid gold chalice and paten preserved at Corpus Christi College, Oxford, the gift of the founder, Bishop Fox. These have the year-mark K for 1507-8. See *Quart. Rev.*, cxi. p. 353.

¹ See Riaño, *Industrial Arts in Spain*, 1879; and Davillier, *L'orfèvrerie en Espagne*, 1879.

² *Archæol.*, xxvi. 422.

early examples of this form of chalice have the bowl mounted in bands, set with jewels, and enriched with minute filigree work,—a design which appears to have been taken from those cups, such as the four magnificent examples in the treasury of St Mark's at Venice, which have their bowl cut out of crystal, onyx, or some other precious stone.¹ The finest examples of this class are the Ardagh chalice, now in the Dublin Museum, and the chalice of St Remigius, in Rheims cathedral; both are most magnificent specimens of the taste and skill of 11th-century goldsmiths. C shows the next form (12th and 13th centuries). The design is simpler; there is a distinct shaft, extending above and below the knob; and on the foot is marked a cross, not found in the earlier ones, to show which side the priest is to hold towards himself at celebration. The next alteration in the form of chalice,

FIG. 16.—Various shapes of Chalices, showing development from the earliest form.

which occurred in the 14th century, was to make the foot not circular in plan but polygonal or lobed, so that the cup might not roll when laid on its side to drain, after it had been rinsed out. It thus took the shape D, and this form lasted in most countries till about 1500, and in England till the Reformation. In countries which did not adopt the Reformed faith the shape was altered, by the general growth of the Renaissance, into a form frequently like E. But in England the change was more complete; the bowl, which in the previous two or three centuries had been slowly reduced in size, owing to the gradually introduced practice of refusing the wine to the laity, was suddenly made more capacious, and the form was altered to the shape F, in order that the Protestant "communion cup" might bear no resemblance to the old Catholic "massing chalice." This was ordered to be done in 1562, (see *Arch. Jour.* xxv. 44–53). The last form, G, shows the usual shape of sepulchral chalices, which, before the Reformation, were enclosed in the coffins of all ecclesiastics who had received priest's orders. These are without the knob, and were frequently made of pewter, tin, or even wax, as they were not meant for use. In some few cases a real chalice was buried with some ecclesiastic of rank, but this was exceptional.

Secular plate during the 15th and 16th centuries was very similar in style to that made in Germany, though the English silversmiths of the latter century never quite equalled the skill or artistic talent of the great Nuremberg and Augsburg silver-workers. In the 17th century, during the reigns of James I. and Charles I., many fine pieces of plate, especially tall hanaps and tankards, were made of very graceful form and decoration. The greater part of this, and all earlier plate, especially the fine collections belonging to the universities, were melted down during the Civil War. In Charles II.'s reign returning prosperity and the increase of luxury in England caused the production of many magnificent pieces of plate, often

on a large scale, such as toilet services, wine-coolers, and even fire-dogs and tables. These are very florid in their ornament, and mostly have lost the beautiful forms of the century before (fig. 17). In the early part of the

FIG. 17.—Covered Cup of solid gold, 6 inches high, circa 1660–70. Given to Exeter College, Oxford, by George Hall, Bishop of Chester.

18th century the designs are mostly poor, and the decoration rather coarse, till the time of the classical revival which was brought about mainly by the discovery of the buried cities of Pompeii and Herculaneum. A quite different style of plate then came into vogue—semi-classical both in form and decoration, and often worked with great delicacy of treatment. A good deal of plate in this style was made under the influence of the brothers Adam (fig. 18), distinguished architects in the second half of the 18th century. Of modern plate from the art point of view there is nothing to say; it is nearly always poor in design and feeble in execution.

The Assay of Gold and Silver Plate.—The primitive method of testing the purity of the metal was by marking a streak with it on the touch-stone, and comparing the colour of the mark with that made by various pieces of gold or silver of known degrees of purity. Assay by cupellation is now employed for silver: a piece of the silver to be tested is melted with some lead in a cupel or bone-ash crucible; the lead is oxidized, and rapidly sinks into the bone-ash, carrying with it any other impurities which are present. The residue of pure silver is then weighed, and by its loss shows how much alloy it contained. Gold is now tested by an elaborate chemical process by which the trial bit is dissolved in acid, and then thrown down in the form of precipitate, which can be examined by a careful quantitative analysis. See ASSAYING, GOLD, and SILVER.

The standard of purity required in the time of Edward I. was, for gold, that it should be of the "Paris touch," *i.e.*, 19½ carats out of 24. Before then 22 carats was the standard. Silver was to be "of the sterling alloy," *viz.*, 11 oz. 2 dwts. to the pound. Except for a time during the 16th century, this standard of silver has been kept up, and is still required by law.

Hall-marks on Silver.—In the 13th century the English Guild of Gold- and Silver-smiths had grown into great importance, and had acquired monopolies and many special privileges. In order to keep the standard up to the required purity the system of requiring each article to be stamped with certain marks was introduced by royal command. The first of these was the *King's mark*—a leopard's or lion's head crowned. This was introduced in 1300 by Edward I. (29 Edw. I. stat. 3, c. 30). The second, the *Maker's mark*, was added in 1363 (37 Edw. III. c. 7). This might be any badge or initial chosen by the master silversmith himself. The third was the *Year letter* or *Assayer's mark*; this was an alphabet, one letter being used for a year, counting from the day of the annual election of the warden of the Goldsmiths' Company. When one alphabet was exhausted, another with differently shaped letters was begun. The first of these series of year-letters commences in 1438. The earliest existing piece of plate which has the three marks

FIG. 18.—Silver Vase, 11 inches high, dated 1772. Designed by the brothers Adam. (S. K. M.)

¹ See De Fleury, *La Messe*, Paris, 1882, in progress.

complete is a spoon which was given by Henry VI. to Sir Ralph Pudsey; this has the year mark for 1445. Other marks, subsequently introduced, were the lion passant, first used in 1545; the lion's head erased, and a full-length figure of Britannia, used only between 1697 and 1720; and lastly the portrait of the reigning sovereign, which has been in use since 1784. In addition to these general hall marks, the plate made in various towns had from the year 1423 certain special provincial marks. The best work on hall-marks' company, and the marks themselves, with the history of the Silversmiths' Company, is Cripps, *Old English Plate*, 1881. See also Cripps, *Old French Plate*, 1880.

The South Kensington Museum has a very fine illustrative collection of plate, from early mediæval times downwards. It also possesses a very valuable and large assortment of electrotype copies, including the Hildesheim and a part of the Petrossa treasures, as well as a number of the best specimens of college and corporation plate. The museum handbooks on this subject by J. H. Pollen and W. Cripps are extremely useful to the student. The same department has also published a most valuable *List of Works on Gold- and Silver-smiths' Works in the National Art Library*, 1882.

Modern Plate in the East.—Though little plate of real artistic merit is now made in Europe, in the East, among the Moslem and Hindu races, there still survive some real taste in design and skill in execution. Delhi, Benares, Lucknow, Cutch, and other places in India and Kashmir still produce a quantity of beautiful silver and gold work,—chiefly ewers, basins, rose-water sprinklers, salvers, coffee-pots, and the like. These are of graceful form, covered with rich repoussé work, or more often with very delicate chased patterns. Their style in the main is Moslem, but some combine an Arab form with native Indian surface decoration. This class of work is not a revival, but has been practised and handed down by unbroken tradition, and with little or no change in style from the 16th century or even earlier.¹ The silversmiths of Persia, Damascus, and other Eastern places are still skilful, and retain some good tradition in their designs. They are, however, more occupied in the production of personal ornaments than in making larger works of silver or gold.

(J. H. M.)

PLATE, THE RIVER, or RIO DE LA PLATA ("River of Silver"), in South America (see vol. ii. Plate xxv., and vol. iv. Plate xvii.), was at first known as Rio de Solis, after Juan Diaz de Solis, who discovered it in 1515, and lost his life on its banks. The present name, a double misnomer, was bestowed by Sebastian Cabot, who, ignorant that he was on the wrong side of the continent, thought he had reached a country of mineral wealth—a mistake (perpetuated also in the designation Argentine Republic) which may be said to have received a kind of poetic justification in the fact that the distant mines of Potosi lie within the drainage area of the La Plata system. Like Rio Grande do Sul and Rio de Janeiro on the Brazilian coast, this Rio is not a river but a vast estuary into which rivers discharge. At its narrowest it is 23 miles across, opposite Buenos Ayres 34 miles, and opposite Montevideo 63 miles. By some writers the conventional limit between estuary and ocean is drawn from Montevideo, where the water is still fresh enough to be drunk; but others go farther out and take the line 150 miles across from Maldonado to Cabo San Antonio. In the former case the length of the estuary is 125 miles. At one time it must evidently have extended 200 miles farther inland to Diamante, at the bend of the Paraná; and nature is steadily and rapidly at work prolonging the rivers proper at the expense of the estuary. At low water the average depth may be taken at 18 feet, and shoals and sandbanks are abundant, especially in the upper end. Nearly the whole expanse between Buenos Ayres and Martin Garcia Island is between 3 and 6 feet deep, and a great portion is even shallower. In the shallower portions the bottom consists of a very fine hard-grained sand, in the deeper portions of a sticky ooze. The tidal movement is so disguised by the more obvious effects of wind that Mr Révy found people who had lived all their lives on the banks ready to deny its existence. But at Buenos Ayres the normal neap-tide is 5 feet 3 inches above ordinary low water, and the spring tides vary from 6 to more than 10 feet. The region being one of "storms and extraordinary electric disturbance," with the pampero at one time blow-

¹ See Birdwood, *Industrial Arts of India*, 1880, p. 144.

ing hard from the land and at another a sea wind driving the ocean before it, the ordinary levels and currents are often violently disturbed. The general slope of the surface may even be reversed, and the main current of estuary and river run up stream for a hundred miles or more. It has been estimated that the volume of water poured into the Rio de la Plata exceeds the aggregate discharge of all the rivers of Europe put together. Nor need this be matter of surprise when the enormous extent and the character of the drainage area are taken into account. The headwaters of the Rio Blanco (a feeder of the Pilcomayo sub-system) rise only 125 miles from the coast of the Pacific, in $68^{\circ} 10'$ W. long., and those of the Rio Grande are not more than 70 miles from the coast of the Atlantic, in 44° W. long.; the basin thus extends east and west over twenty-four degrees of longitude, or 1500 miles, and the direct distance from the northmost source to the mouth of the Paraná is about as great. A considerable proportion of this vast area lies within the tropics, and receives an abundant rainfall, which, owing to the character of the strata, is largely carried off by the surface drainage. As an instance of the effect of this rainfall on even the secondary tributaries, Mr Bigg-Wither's experience may be cited: at Jatahy on the Tibagy he was detained from the 2d to the 25th of July by the river, after nine days of incessant downpour, rising 33 feet at a place where it was 200 yards wide, and pouring along a volume of 90,000 cubic feet per second, or twenty-five times its low-water volume (see *Journ. Roy. Geogr. Soc.*, 1876).

The three great rivers of the La Plata system are the Paraná, its equal affluent the Paraguay, and the Uruguay—the second being the most important as a waterway, and the first the most interesting from its physical features.¹ As the general course of the Paraná and the Paraguay, both of which rise in Brazil, has already been sketched in the article on that country (vol. iv. p. 222), it simply remains to direct attention to a few points of interest. In regard to the great "Seven Falls" of the Paraná, we have still no better account than that of Azara in the 18th century; but the Hundred Cataracts or Victoria Falls of the Curityba or Y-guazu have been described in detail by the members of the first Germano-Argentine colonial land-surveying expedition to Misiones in 1883 (see *Verhandl. d. Ges. f. Erdkunde zu Berlin*, vol. x. pp. 357–364). For combined beauty and grandeur of scenery they claim to rank among the foremost cataracts in the world. About 6 or 7 miles higher up the river is 3 miles broad; it gradually narrows until, after passing through a perfect labyrinth of islands (King Albert Archipelago), it pours, not in a single mass, but in numerous streams, over a horse-shoe edge of rock into a gorge 120 to 150 feet deep. Niederlein divides the falls into three groups—a northern or Brazilian, a central or insular, and a southern or Argentine, to which he has attached respectively the names of the Emperor Don Pedro, the Emperor William, and General Roca. The river continues for some distance shut in by overhanging cliffs; and a large number of secondary cataracts (Bosetti Falls, Prince Bismarck Falls, &c.) are formed by tributary streams, and add to the bewildering beauty of the scene.

The watersheds between the north-eastern headwaters of the Paraguay system and the southern affluents of the Amazons are so low and narrow that in some instances canoes have been conveyed overland from the one to the other. Interest has recently been concentrated on the exploration of the Pilcomayo, a right-hand tributary which joins the Paraguay proper in $25^{\circ} 20'$ S. lat. Though its sources have long been known, all attempts to trace it downward from Bolivia or upward from the Argentine Republic

had been foiled by the hostility of the Indians. At length, on April 27, 1882, Dr Crevaux, the great French explorer of South-American rivers, was slain with all his party by the Tobas at a place called Ipanticapu. General interest was thus aroused; and the task in which Dr Crevaux perished has since been practically accomplished by Dr Thouar, his fellow-countryman, who, leaving the San Francisco mission-station on 10th September 1883, reached the mouth of the river on 10th November, though he had not been able to keep close to its course in the lower section of the journey. The Pilcomayo rises in Vilcapujia (a mountain 13,500 feet high to the E. of Lago Poopo), and passes between the Cordillera of Livichuco and the Cordillera de los Frailes, a few miles to the north of Potosi. It cuts through the last range of the Andes in $21^{\circ} 16' 50''$ S. lat. and $63^{\circ} 25'$ W. long., and enters the plains of the Gran Chaco at a height of 1456 feet above sea-level (J. B. Minchin²). It is soon after joined by the Pilaga, which brings down the waters of the Rio Blanco and other streams from the mountains. Till in its south-eastern course it reaches 22° S. lat., the river has a very regular course, flowing at the rate of 6500 feet per hour over a sandy bed 600 to 700 feet wide, unimpeded by rocks or trees, and enclosed by steep banks 15 to 20 feet high, above which the country stretches out in pasture-covered plains. Farther down the banks increase in height to from 20 to 45 feet, and embrace a channel or valley 5500 feet or more in breadth, though the actual river does not exceed 150 or 200 feet. At the point called Cabello Muerto, $24^{\circ} 20'$ S. lat., commence the marshy plains of the lower course, in which the banks hardly rise above the level of the water, and a whole series of lagoons lie at a distance of a mile or two on the left hand. So flat is the country, and so tortuous the river that when Mr Robinson, in 1873, ascended for 150 miles, he never lost sight of the white houses of Asuncion.³

About 150 miles below the mouth of the Pilcomayo the Paraguay is joined by another Andean river the Rio Vermejo or Y-pyta, whose red waters, pouring into the dark clear water of the main stream, are sufficient to tinge the whole current downwards to the confluence of the Paraná. "From the junction of its headstreams down to the Paraguay, the Vermejo does not receive a single affluent; its breadth varies from 70 to 250 yards, its depth from 5 to 16 feet; and the current appears to average $1\frac{1}{2}$ miles an hour" (Keith Johnston). Its navigability was shown about 1780 by the Franciscan missionaries Murillo and Lapa descending the whole way in a canoe, but it was not till 1874 that, under Don Natalio Roldan, the regular navigation was undertaken.

At their confluence the Paraguay has a width of half a mile, the Paraná of 3 miles. The united river continues for 686 miles, first in a south-south-west, then in a south, and finally in a south-east direction before it reaches the head of the La Plata estuary. Down to Diamante, or for 433 miles, its left bank is at intervals formed by lines of bold bluffs from 100 to 200 feet high, on which several of the more important towns are built; but the channel often breaks up so as to enclose extensive islands. The worst reach in this respect is the 45 miles below Goya, a little town in $29^{\circ} 7'$ S. lat. At Diamante begins the enormous delta (some 5000 or 6000 square miles) which is traversed by countless and changing channels, and presents nothing else, even if viewed from the masthead of the steamer, but a boundless labyrinth of islands clothed with exuberant vegetation. The two chief lines of navigation through this deltaic region are the Paraná de las Palmas (so called by Cabot, in 1526, but now showing comparatively few palms among its ceibos, willows, and poplars) and the Paraná Guazu. The former has its mouth about 24 miles north of Buenos Ayres, the latter joining the estuary of the Uruguay 22 miles farther north, in 34° N. lat. and $58^{\circ} 24' 30''$ W. long.

The third great confluent of the La Plata system, the Uruguay, is quite unlike the other two. Instead of having a fairly steady and continuous flow, it appears sometimes as an insignificant torrent and at other times as a magnificent river. It has its headwaters in the Serra Geral, and for several hundred miles continues to flow west through Brazil (forming the northern boundary of Rio Grande do Sul province), as if it meant, like the Curityba, to carry its waters to the Paraná; but about 54° W. long. it is turned aside by the mountain range of Misiones, and flows south-west and south almost parallel with the Paraná. It has a total length of 950 miles, and a drainage area of 200,000 square miles.

In the matter of annual rise and fall the three rivers differ considerably. The Paraguay is regular, reaching its lowest stage in the end of February, and its highest about the end of June, and showing an average difference of level not exceeding 15 feet. The ordinary flow at Asuncion is between 97,400 and 99,950 cubic feet per second. Above the junction of the Paraguay the Paraná appears to have numerous and rapid risings at irregular intervals, but to reach its maximum in December. Below the junction it has much the same movement as the Paraguay, having high water in sum-

¹ The word Paraná, meaning simply *river*, appears, it is to be remembered, alone or in composition again and again throughout South America. See Lallemand, in *Zeitschr. für Erdk.*, Berlin, 1863, p. 156.

² "Eastern Bolivia, &c." in *Proc. Roy. Geo. Soc.*, 1881.

³ See Thouar's account in *L'Exploration*, 1884; and map of the Pilcomayo in *Bol. Inst. Geogr. Argentino*, 1882.

mer, gradually shrinking through September, October, and December, flooding in January, and continuing high and steady till June. The Uruguay rises about the middle of January (at Salto sometimes 22 feet above low water); again in April, to continue in flood for two months (30 feet at Salto); and for the third time, and with great regularity, in September or October, to last a whole month, and reach 40 to 50 feet above low water. Occasionally the flood level of the Paraná is maintained throughout a whole year, or even two years in succession; and at intervals, as in 1858 and 1868, the water rises so high that the whole delta is submerged. The highest floods on record stood 24 feet above ordinary low-water mark at Rosario, or 12 feet above ordinary high water. As a system of waterways the La Plata rivers are but partially developed. Steamers, mainly Brazilian, ascend from Buenos Ayres by the Paraná, Paraguay, and Cuyabá, a total distance of 2146 miles, to the town of Cuyabá in Brazil; and the Pilcomayo and the Vermejo, the Apa, the Jeju, and the Tebiquary are all more or less navigable. The Paraná affords a free passage for 280 miles above the confluence to the Seven Falls, except during low water, when the rapids of Aipe interfere; and, according to Bigg-Wither, the upper Paraná and its tributaries the Tibagy, Paranapanema, Tiete, Ibahy, &c., furnish 1290 miles of navigable stream, of which 510 could be at once utilized by steamers of light draught, while the remainder would require a certain outlay in the way of improvements. Vessels drawing 4½ feet of water can always ascend the Uruguay to Salto (200 miles), and during six months they can cross the Salto Chico, or Lesser Fall, a mile higher up; but the Salto Grande, 8 miles farther, stops all progress except during six weeks in October and September. The whole system may be estimated to give upwards of 5000 miles of waterway, of which 3500 are accessible from the sea, without counting the secondary deltaic channels.

See T. S. Page, U.S.N., *La Plata*, 1859 (the surveys of the "Waterwitch"); Burton, *Battle-fields of Paraguay*, 1870; Bigg-Wither, *Pioneering in South Brazil*, 1878; J. J. Eévy, *Hydraulics of Great Rivers: the Paraná, the Uruguay, and the La Plata Estuary*, 1874 (a series of elaborate investigations and measurements of great value); and other works mentioned under PARAGUAY. (H. A. W.)

PLATEAU, JOSEPH ANTOINE FERDINAND, was born at Brussels in 1801, and died in 1883 at Ghent, where he had been professor of physics from 1835. He was a pupil and friend of Quetelet, who had much influence on the early part of his career. The more original investigations of Plateau refer chiefly to portions of one or other of two branches of science—physiological optics and molecular forces. His doctoral thesis (Liège, 1829) had for its subject "Impressions produced by Light on the Organs of Vision"; and it was succeeded by numerous memoirs, some of much value, on the persistence of visual impressions, subjective impressions of colour, irradiation, &c. Among other results of his studies was the invention of the philosophical toy known as the "thaumatrope." We owe to him also something much more important, the process of studying the motion of a vibrating body by looking at it through equidistant radial slits in a revolving disk. In 1829 he imprudently gazed at the midday sun for 20 seconds, with the view of studying the after effects. The result was blindness for some days, succeeded by a temporary recovery; but for the next fourteen years his sight gradually deteriorated, and in 1843 he became permanently blind. This calamity did not interrupt his scientific activity. Aided by his wife and son, and afterwards by his son-in-law Van der Mensbrugghe, he continued to the end of his life his researches on vision,—directing the course of the experiments which they made for him, and interpreting the bearing of the results. He also published a valuable analytical catalogue of all the more important memoirs which had been written, from the earliest times to the end of the 18th century, on his favourite theme of subjective visual phenomena. But even more extraordinary were this blind man's investigations about molecular forces, embracing hundreds of novel experiments whose results he saw only with others' eyes. These form the subject of his great work *Statique expérimentale et théorique des Liquides soumis aux seules Forces moléculaires* (2 vols., 1873), which is a valuable contribution to our knowledge of the phenomena usually called capillary. To avoid, as far as possible, complications due to gravity, Plateau employed either films formed of a solution of soap with

glycerin, or masses of oil suspended in a mixture of alcohol and water of the same density as the oil. See CAPILLARY ACTION.

PLATED WARE. The plating or coating of one metal or alloy with another is extensively practised in metal working. In some cases the coating metal is a valuable protector from oxidation, &c., of the underlying metal; in other cases the properties and advantages of two metals—such as strength and lustre—are combined in one object; and more frequently a cheap and inferior body by a superficial coating gets the appearance of a more valuable and important metal. The art of plating was originally applied to the production of imitation silver plate, whence the term "plating." The original method of silver plating consisted in attaching, by a kind of autogenous soldering, thin plates of silver to the opposite surfaces of a prepared ingot of copper alloy or of German silver. The silver plates were firmly wired to the ingot and submitted to a soldering temperature in a plating furnace, in which the surfaces became firmly united. Subsequently the ingot was rolled down to a sheet in which the relative thickness of the metals was maintained, and from such sheets "silver plated" articles were fashioned. This method of plating may be regarded as now extinct, being superseded by electro-plating (see ELECTRO-METALLURGY, vol. viii. p. 114). Recently, however, cooking vessels, &c., of iron plated in an analogous manner with nickel have come into use (see NICKEL, vol. xvii. p. 488). The plating or casing of iron with brass is extensively practised in the manufacture of stair-rods, curtain and picture rods, and "cased" tubing for upholstery purposes generally; and in the manufacture of pipes for conveying water the body of lead is frequently lined with a coating of pure tin. The gilding of metals is a process analogous to plating, as are also the galvanizing of iron and the manufacture of tin andterne plates. For these see IRON, vol. xiii. p. 357.

PLATEN-HALLERMUND, AUGUST, GRAF VON (1796–1835), German poet, was born at Ansbach on October 24, 1796, and died at Syracuse on December 5, 1835. His principal publications were *Lyrische Blätter* (1821), *Sonette aus Venedig* (1825), an historical fragment entitled *Geschichten des Königreichs Neapel 1414–43* (1833), and a poem in nine cantos, *Die Abbasiden* (1835). He wrote also a number of dramas, of which may be mentioned *Der gläserne Pantoffel* and *Die Liga von Cambrai*. See vol. x. p. 545.

PLATINUM AND THE PLATINUM METALS. The metals platinum (Pt), palladium (Pd), rhodium (Rh), iridium (Ir), ruthenium (Ru), and osmium (Os) are united into a family by a striking similarity in chemical characters and by their association in natural occurrence. A rather rare ore, called platinum ore or polyxene, is almost the only native material which is available for their extraction; it contains them all in the reguline form. *Traces* of platinum are found in almost all native gold.

As early as the first half of the 16th century it appears to have been noticed that the gold ore in the Spanish mines of Darien includes grains of a white metal, endowed with the qualities of a noble metal and yet distinctly different from silver; but the fact remained unknown in Europe because the Spanish Government, having found out that the new metal lent itself most admirably for the adulteration of gold, prohibited its exportation. Only from about the middle of last century did the metal begin to find its way to Europe and to become known there, at first as a curiosity, under its Spanish name of "platina del Pinto" (the little silver from the river Pinto). Its chemical individuality and qualities were established by the successive labours of Scheffer (1752), Marggraf (1757), Bergmann (1777), and others. An amateur, Count von Sickingen, it appears, was the first who succeeded in work-

ing the metal (1772); the first platinum crucible was produced by Achard (1784). Achard's mode of rendering the native metal amenable to mechanical working was founded upon the fact that it forms a readily fusible alloy with arsenic, from which the latter can be driven off again by intense heating. This method was worked industrially for a time, but subsequently superseded by another superior process, which is usually credited to Wollaston, because it was he who, after having wrought it as a rich source of revenue for years, published it in 1828. But as early as 1800 Knight of London had published all that is essential in the process; and Messrs Johnson, Matthey, & Co. inform the writer that Wollaston obtained the secrets of both the refining and the compressing of the spongy into compact metal from a relative of theirs, Thomas Cock, who, they are convinced, is the true inventor. Undisputed merits of Wollaston's are his discoveries of palladium (1803) and rhodium (1804). About the same time iridium and osmium were discovered by Smithson Tennant.

Platinum ore well deserves its cognomen of "polyxene," because it is a most complex mixture of mineralogical species, including (1) a number of heavy reguline species designated as platinum, osmiridium, iron-platinum, platinum-iridium, iridium, palladium (also gold), and (2) a number of non-metallic species, notably chrome-iron ore, magnetic oxide of iron, zircon, corundum, and occasionally also diamond. The reguline components always form detached granules, which are generally small, but occasionally assume considerable dimensions. The Demidoff museum contains a native platinum lump weighing 21 pounds troy. The ore, as already stated, was discovered first in South America; it is found there chiefly in the provinces of Choco and Barbacos, New Granada, and also in Brazil. It occurs besides in San Domingo, in California, at the Rogue river in Oregon, in Canada, and in the island of Borneo. But the richest deposits are those of the Ural Mountains; these were discovered about 1823, and have been wrought by the Russian Government since about 1828. Part at least of the Ural ore, as Daubré showed, was embedded originally with chrome-iron in a serpentine derived from olivine. The very variable percentages of the several components range approximately as follows:—platinum, 60 to 87; other polyxene metals 3 to 7; gold up to 2 and more; iron 4 to 12; copper 0 to 4; non-metallic gangue 1 to 3.

Platinum, though a noble metal chemically, has too modest an appearance to lend itself much to the jeweller's purposes. The Russian Government used, for a while, to strike platinum coins, but soon came to give up the practice on account of the immense fluctuations in the commercial value of the metal. Almost all the platinum produced now-a-days is made into chemical utensils. Platinum, in fact, is the metal of the chemist. "Without platinum crucibles, which share the infusibility of porcelain with the chemical inertness of gold ones the composition of most minerals could not have been ascertained" (Liebig), and chemistry generally could not have come up to its present level. In industrial chemistry platinum is used chiefly for the construction of those stills for the concentration of oil of vitriol which, although a single one costs a fortune, are cheaper in the long run than glass retorts.

The technical extraction of platinum from its ore is to the present day effected everywhere by some modification or other of the so-called "Wollaston" process. Heraeus of Hanau operates as follows. The ore is digested within glass retorts in aqua regia diluted with three times its weight of water, an over-pressure of some 12 inches of water being established within the retorts to accelerate the process, which always takes several days. The whole of the osmiridium, along with more or less of other polyxene metals, and the "sand" (corundum, chrome-iron, &c.) remain undissolved, as a heavy black deposit; the platinum, palladium, part of the rhodium, and more or less of the other three

polyxene metals pass into solution, the platinum, iridium, and palladium as tetrachlorides. From the clarified solution the whole (almost) of the platinum can be precipitated as $\text{PtCl}_6(\text{NH}_4)_2$ by addition of a large excess of sal-ammoniac; and this simple process used to be adopted formerly. But the precipitate then includes much chloro-iridate of ammonium $\text{IrCl}_6(\text{NH}_4)_2$ and other impurities. Heraeus, therefore, first evaporates to dryness and heats the residue to 125°C . for a sufficient time, to reduce the palladic and iridic chlorides to the lower stages of PdCl_2 and Ir_2Cl_6 , which form soluble double salts with sal-ammoniac. The heated residue is dissolved in water acidulated with hydrochloric acid, the solution filtered, and mixed with hot concentrated solution of sal-ammoniac; when a (relatively) pure chloroplatinate comes down as a yellow precipitate (the iridium compound is dark-red), which is washed, first with saturated sal-ammoniac solution, then with dilute hydrochloric acid. The precipitate needs only be exposed to a dull red heat to be converted into "spongy platinum," i.e., metallic platinum in the form of a grey porous mass. As platinum is infusible even at the highest temperature producible in a wind-furnace, the spongy metal cannot be fused together into a regulus like an ordinary metal; but it shares with wrought iron the rare quality of assuming a high degree of softness and viscosity at a strong red heat; and consequently the sponge, after a preliminary compression by purely mechanical means, needs only be exposed to a strong heat to "frit" into a coherent mass; and this mass, by repeated forging at a white heat is readily made into a perfectly homogeneous compact bar, which, as the metal is very ductile, is easily rolled out into sheet or drawn into wire. In the former form more especially it goes into the workshop to be made into utensils.

This process of welding at the time of Achard (who used it first) and of Knight was a necessary make-shift; but it is singular that it was retained long after the invention of the oxyhydrogen blast (see vol. xviii. p. 105), by means of which platinum can be fused as easily as lead can in an ordinary fire. With the oxyhydrogen-blowpipe Hare, as early as 1847, fused 970 grammes (upwards of two pounds) of platinum into one regulus. Yet platinum manufacturers did not utilize this obvious process until Deville and Debray, in 1859, again demonstrated its practicability. Their furnace is of the simplest description. Two flat pieces of quicklime, scooped out so as to represent two cupels, are placed one upon the other so that they enclose a flat space similar in form to two superimposed soup-plates. The lower cupel has a notch cut out of its side to serve as a spout for pouring out the liquefied metal, the upper and shallower one is pierced with a central slightly conical round hole through which the (platinum) nozzle of the blowpipe enters, so that the flame flattens itself out on the introduced metal. By means of this simple contrivance Deville and Debray had no difficulty in fusing as much as twelve kilogrammes of platinum into one regulus; and Messrs Johnson, Matthey, & Co. of London now think nothing of fusing up as much as 1000 ounces of metal in one operation. A regulus made under Mr Geo. Matthey's superintendence for the metric commission in Paris in 1874 weighed one quarter of a ton.

The shaping of compact platinum is effected pretty much in the same way as that of gold or silver; only the difficulties are less because platinum, unlike the two ordinary noble metals, is susceptible of "welding"; i.e., two pieces of the metal, at a white heat, can be united into one by a stroke of the hammer. Soldering is rarely necessary; it used to be effected (and still is occasionally) by means of gold as a connecting medium and an ordinary blowpipe. But platinum workers, following the lead of Messrs Johnson, Matthey, & Co., have long learned to unite two platinum seams by the "autogenic" process—the local fusing of the two contiguous parts in the oxyhydrogen flame.

For the preparation of chemically pure platinum Schneider's process is the one most easily executed and explained. The commercial metal is dissolved in aqua regia and the excess of nitric acid removed by evaporation to a syrup in a water-bath. The residue is redissolved in water and boiled for a long time with a large excess of potash-free caustic soda. If care be taken to maintain a strong alkaline reaction, all the foreign polyxene chlorides are reduced to lower forms than that of tetrachloride; while only the platinum itself retains this state of combination. The hypochlorite formed is then reduced (to NaCl) by addition of a little alcohol to the boiling alkaline liquid, which is now allowed to cool and acidified strongly with hydrochloric acid so as to redissolve any hydrated platonic oxide which may have been precipitated by the first instalments of acid. The liquid at last is filtered, and precipitated by sal-ammoniac to obtain a pure chloroplatinate ($\text{PtCl}_6(\text{NH}_4)_2$), which, on ignition, of course, yields an equally pure spongy metal.

Pure compact platinum is a tin-white metal about as soft as pure copper and nearly (but not quite) equal in plasticity to gold. The specific gravity of the fused metal is 21.48 to 21.50 at 17.6°C . (Deville and Debray). The breaking strain is 34.1 kilos for hard-drawn and 23.5 kilos for annealed wires; the modulus of elasticity 15,518 (kilogramme and millimetre as units; by Werthum's ex-

periments on annealed welded wire). Unit length of the (fused) metal expands by 0.000907 from 0° to 100° C. (Fizeau). The specific conductivity for heat at 12° C. is 8.4, for electricity at 0° C. 16.4 (silver=100). The statement regarding electricity refers to the annealed metal. The fusing point, according to recent determination by Violle, is 1779 C.; the same experimenter finds for the true specific heat $\delta Q/\delta t = 0.0317 + 0.000012t$ (centigrade scale). When platinum is heated beyond its fusing point, it soon begins to volatilize. The fused metal, like silver, absorbs oxygen, and consequently "spits" on freezing. At a red heat the then viscid metal, as Graham has shown, "occludes" hydrogen gas; i.e., it dissolves the gas (just as, for instance, liquid water would), which explains the fact previously discovered by Deville that a platinum tube, although it may be perfectly gas-tight in the cold, at a red heat allows hydrogen (but not, for instance, oxygen, nitrogen, or carbonic acid) to pass through its walls. According to Graham the quantity of gas occluded is independent of the surface of the metal operated on, but proportional to its weight. No gas is taken up in the cold; but the gas occluded at a red heat, though extractable at that temperature by means of an absolute vacuum as producible by a Sprengel pump (see MERCURIAL AIR PUMP, vol. xvi. p. 20), is retained on cooling and cannot be thus liberated at the ordinary temperature. The volume of hydrogen absorbed by unit-volume of metal at a red heat under one atmosphere's pressure was found, in the case of fused metal, to vary from 0.13 to 0.21 volume measured cold; in the case of merely welded metal, from 2.34 to 3.8 volumes (compare *Palladium* below). Oxygen gas, though absorbed by the liquid, is not occluded by the solid metal at any temperature, but when brought in contact with it at moderate temperatures suffers considerable condensation at its surface. The thin condensed film of oxygen exhibits a high degree of chemical activity: a perfectly clean piece of platinum foil, when immersed in a mixture of hydrogen or ammonia or other combustible gas and air, begins to glow and starts a process of slow combustion or there may be an explosion. The spongy metal of course exhibits a very high degree of activity: a jet of hydrogen gas when made to strike against a layer of spongy platinum causes it to glow and takes fire. This is the principle of the (now defunct) Döbereiner lamp. But the most striking effects are produced by a peculiar kind of very finely divided platinum, which was discovered by Liebig and called by him platinum black on account of its resemblance to lamp-black. A particularly active "black" is produced by dropping platinum chloride solution into a boiling mixture of three volumes of glycerin and two of caustic potash of 1.08 specific gravity. Platinum black, according to Liebig, absorbs 800 times its volume of oxygen from the air, and in virtue thereof is a most active oxidizing agent, which, in general, acts "catalytically" because the black, after having given up its oxygen to the oxidizable substance present, at once takes up a fresh supply from the atmosphere. For examples see FERMENTATION, vol. ix. pp. 94-98.

Platinum Alloys.

Platinum alloys of almost any kind are easily produced synthetically; and, as a rule, a temperature little if at all above the fusing point of the more fusible component suffices to start the union. We will begin with the cases in which the metal combines with another member of its own family. *Iridium*.—In the heat of an oxyhydrogen flame the two metals unite permanently in all proportions. The alloy has pretty much the appearance of platinum, but it is less fusible, harder, more elastic, specifically heavier, and less readily attacked by aqua regia,—all these qualities increasing as the percentage of iridium increases. The 19 per cent. alloy was produced for the first time by G. Matthéy. It has the hardness and elasticity of soft steel (modulus of elasticity=22,000 for millimetre and kilogramme), and is hardly attacked by aqua regia. Alloys richer in iridium are difficult to work. The 10 per cent. alloy on the other hand still retains enough of the virtues referred to to be far superior to platinum itself—perhaps we might say, to any other solid—as a material for standard measures of length or weight. In 1870 Messrs Johnson, Matthéy, & Co. exhibited a standard metre made of this alloy, and it gave such unqualified satisfaction that the international metric committee which sat in Paris some years ago adopted it for the construction of their standards. *Rhodium*.—An alloy of 30 per cent. of this metal and 70 of platinum is absolutely proof against aqua regia, but is very expensive. Deville and Debray once elaborated an igneous process for producing, directly from the ore, a triple alloy of platinum, iridium, and rhodium, which is quite workable and, besides being more highly infusible than platinum, is almost proof against aqua regia. Crucibles made of this alloy used to be sold in Paris and elsewhere at moderate prices; but they are now no longer to be had. *Gold*.—This metal unites with platinum in all proportions, forming greyish-yellow or greyish-white alloys. A graduated series of these alloys was recommended by Schertel and Ehrhard as a means for defining certain ranges of high temperatures. According to their experiments, while the fusing-point for gold was 1075° C., and for platinum 1775°, it was 1130° for 10 per cent. of platinum, 1190°

for 20, 1255° for 30, 1320° for 40, 1385° for 50, 1460° for 60, 1535° for 70, 1610° for 80, and 1690° for 90 per cent. *Silver* and platinum unite readily in any proportion, but the alloys are in general liable to "liquation" (see METALS, vol. xvi. p. 67). Now platinum is as proof against nitric acid as gold; and yet these alloys cannot, like gold-silver, be parted by means of nitric acid; because, if the alloy is rich enough in silver to be at all attacked by the acid, part at least of the platinum passes into solution along with the silver. But concentrated oil of vitriol effects a sharp separation; the platinum remains. A considerable variety of alloys of platinum with other noble metals are used in mechanical dentistry. The following examples may be quoted:—66.7 per cent. of gold and 33 of platinum; platinum 50, silver 25, palladium 25; platinum 41.7, gold 25, palladium 33.3.

Of the great variety of alloys of platinum with base metals which have been recommended as substitutes for noble metals or otherwise we select the following:—

	Platinum.	Silver.	Copper.	Tin.	Brass.	Nickel
1	19	0	1	0	0	0
2	1	0	26	0	0	0
3	2	1	5	0	2	1
4	1	0	0	10	0	100
5	1	2	0	20	0	100
6	0.5	0	0	15	0	100
7	20	0	0	20	0	100
8	5 to 10	0	0	0	120	60

(1) Known to jewellers and dentists as hard platinum; (2) a rose-coloured fine-grained ductile alloy; (3) introduced by Bolzani in Paris as an imitation gold; (4 to 7) platinum bronzes, recommended—(4) for knife and fork handles, (5) for bells, (6) for articles *de luxe*, (7) for telescopes; (8) not subject to oxidation.

Platinum Compounds.

Platinum is not changed by air, water, or steam at any temperature. It is proof against the action of all ordinary single acids, including hydrofluoric, in the heat or cold. Aqua regia (a mixture of hydrochloric and nitric acids) dissolves it slowly as chloroplatinic acid $PtCl_4H_2$. The metal is not attacked by even very strong boiling caustic potash or soda ley, nor is it changed by fusion with carbonate of soda or potash. Carbonate of lithia, and the hydrates of potash, soda, and baryta, however, when fused in platinum vessels, attack them strongly, with formation of compounds of PtO_2 with the respective bases. According to recent experiments by the writer, none of these reactions go on in the absence of air; hence, for instance, a fusion with caustic baryta or potash can safely be carried out in a platinum crucible if the latter is protected by an atmosphere of hydrogen or nitrogen. Fused hepar (alkaline sulphide) dissolves platinum at a red heat; so does fused cyanide of potassium, especially if mixed with caustic potash.

Chloroplatinic Acid.—The solution of the metal in aqua regia is evaporated down repeatedly in a water bath with hydrochloric acid to destroy the excess of nitric acid and the very concentrated solution allowed to stand, when the acid gradually separates out in brown-red deliquescent crystals of the composition $PtCl_4H_2 + 6H_2O$, which are abundantly soluble in water and also easily in even strong alcohol. The aqueous solution, if free of iridium and platinum chlorides, is of a rich but clear yellow colour free of any tinge of brown. The "chloride of platinum" solution of the analyst is an aqueous solution of this acid. When the solution is mixed with those of certain chlorides, the $2HCl$ are displaced by their equivalent of metallic chloride, and metallic "chloroplatinates" are produced. Of these the potassium (rubidium and cesium) and the ammonium salts are most easily prepared,—by addition of the respective chlorides to a moderately strong solution of chloroplatinic acid; they come down almost completely as pale yellow crystalline precipitates, little soluble in cold water and very nearly insoluble in alcohol. The sodium salt $PtCl_4Na_2 + 6H_2O$ and the lithium salt $PtCl_4Li_2 + 6H_2O$ are readily soluble in water and in aqueous alcohol (the Li_2 -compound dissolves even in absolute alcohol); hence "chloride of platinum" is used for the separation of K , NH_4 , Rb , Cs from Na and Li . On the other hand chloride of potassium or ammonium may serve as a precipitant for platinum, but in this case a large excess of a concentrated solution of the precipitant must be used to bring the solubility of the chloroplatinate precipitate to its minimum. Gold, copper, iron, and many other metals not belonging to the polyxene group, if present, remain dissolved. Real *platinic chloride*, $PtCl_4$, can be produced from the acid $PtCl_4H_2$ only by precipitating from its solution the chlorine of the $2HCl$ by the exact equivalent of nitrate of silver. The filtrate when evaporated (cold) over vitriol deposits red crystals of the composition $PtCl_4 + 5H_2O$. When chloroplatinic acid is heated to 300° C. it loses its $2HCl$ and half the chlorine of its $PtCl_4$ and *platinous chloride*, $PtCl_2$, remains as a dull green powder, insoluble in water but soluble in aqueous hydrochloric acid. Either chloride when heated to redness leaves spongy metal. The hydrochloric solution of platinous chloride, when

evaporated with one of chloride of potassium to a sufficiently small volume, deposits rose-coloured crystals of a double salt $\text{PtCl}_2 \cdot 2\text{KCl} = \text{PtCl}_4\text{K}_2$. From a solution of this double salt *platinous hydrate*, $\text{Pt}(\text{OH})_2$, is obtained, by boiling it with the calculated quantity of caustic soda, as a black precipitate, which, when gently heated, becomes anhydrous. *Platinic hydrate*, $\text{Pt}(\text{OH})_4$, is obtained by boiling chloroplatinic acid solution with excess of caustic soda and then acidifying with acetic acid, as an almost white precipitate, $\text{Pt}(\text{OH})_4 \cdot 2\text{H}_2\text{O}$, which loses its $2\text{H}_2\text{O}$ at 100°C . and becomes brown; at a certain higher temperature it loses all its water and assumes the form of the black anhydride PtO_2 . Both oxides are bases in so far as their hydrates combine with a limited number of acids; towards strong bases they behave as feeble acids. Only a few of the salts of the acid PtO_2 have been investigated. Either oxide when heated to redness breaks up into oxygen and metal.

Platin-Ammonium Compounds.—In this very numerous family of bodies a compound radical containing platinum and some ammonia residue plays the part of a basulous metal. The first member was discovered by Magnus in 1828. By adding ammonia to a hydrochloric solution of platinous chloride, he obtained a green precipitate of the composition $\text{PtCl}_2 \cdot \text{N}_2\text{H}_4$, which soon became known as "Magnus's green salt," and served as a starting point for subsequent investigations.

Platinocyanides.—These were discovered by L. Gmelin, who obtained the potassium salt $\text{Pt}(\text{NC})_4\text{K}_2$ by fusing the metal with prussiate of potash. Martius's method is more convenient: chloroplatinic acid of ammonia is heated in a strong mixed solution of caustic potash and cyanide of potassium as long as ammonia is going off. The solution on cooling deposits crystals containing $3\text{H}_2\text{O}$ of water, which appear yellow in transmitted and blue in reflected light. From the potash salt numerous other platinocyanides can be made by double decompositions; and a very interesting series is derived from these by the addition of chlorine or bromine. All these bodies are distinguished by their magnificent fluorescence.

The Polycene Metals Generally.

The metals all exist in the three forms of "black," "sponge," and compact regulus. The colours of the compact metals are shades of white, except in the case of osmium, which forms blue crystals. Platinum, palladium, and rhodium are ductile; the rest break under the hammer.¹ In regard to specific gravity they arrange themselves into two groups as shown by the following table, which at the same time gives the atomic weights (those of Pt and Ir according to Seubert) and the formulæ of the most stable chlorides:—

Name.	Atomic Weight. O = 16.	Specific Gravity.	Chlorides.
Platinum	Pt = 194.8	21.50	PtCl_2 ; PtCl_4 .
Iridium	Ir = 193.0	22.38	Ir_2Cl_6 .
Osmium	Os = 195	22.48	(?)
Palladium	Pd = 106.6	11.4	PdCl_2 .
Rhodium	Rh = 104.3	12.1	Rh_2Cl_6 .
Ruthenium	Ru = 103.8	12.26	$\text{Ru}_2\text{Cl}_6 + x\text{RCl}$.

The order of fusibility is as follows:—Pd, Pt, Ir, Rh, Ru, Os. Palladium almost fuses in the strongest heat of a wind furnace, but like the four metals following requires an oxyhydrogen flame for its real fusion; osmium has never been fused at all; but it volatilizes abundantly at the highest temperature producible by the oxyhydrogen blast.

Action of Air.—Platinum and palladium do not oxidize at any temperature; rhodium also does not oxidize by itself, but when cupelled with lead it remains as monoxide RhO . Compact iridium does not oxidize appreciably even in the heat; but the finely-divided metal, at some temperature below 800°C ., suffers gradual conversion into Ir_2O_3 , which when heated more strongly begins to dissociate at 800° , and is completely reduced at 1000°C . Ruthenium draws a film of oxide in even cold air; at a red heat it passes into Ru_2O_3 , which retains its oxygen at a white heat. Osmium (the finely-divided metal), when heated in air to about 400°C ., takes fire and burns into vapour of tetroxide, OsO_4 . This and the analogous ruthenium compound are the only volatile oxides of the group.

Water.—None of our metals seem to decompose water or steam at any temperature.

Hydrochloric Acid acts slowly on palladium in the presence of air; otherwise there is no action in any case.

Hot Nitric Acid dissolves palladium as nitrate $\text{Pd}(\text{NO}_3)_2$, and converts finely divided osmium into tetroxide vapour. Compact osmium, and platinum, iridium, and rhodium in any form, are not attacked by the acid.

¹ It still remains to be seen how far this latter statement holds for the absolutely pure metals. Mr George Matthey has succeeded in producing iridium wire, which could be bent into a loop without breaking.

Aqua Regia, in the heat, dissolves palladium (very readily) and platinum (somewhat more slowly) as MeCl_3H_2 ; only the palladium compound is very unstable, being completely reduced to dichloride, PdCl_2 , by mere evaporation over a water-bath. Iridium black, or iridium alloyed with much platinum, dissolves slowly as IrCl_3H_2 , readily reducible (by, for instance, addition of alcohol, or evaporation to dryness and heating of the residue to about 150°C .) to Ir_2Cl_6 . Compact iridium, like ruthenium or rhodium, is hardly attacked even by the hot acid; rhodium exhibits the highest degree of stability. Native osmiridium is not touched by aqua regia. Osmium, in the heat at least, becomes tetroxide.

Free Chlorine combines directly with all polycene metals at suitable temperatures. As a disintegrator it is useful chiefly for the manipulation of osmiridium and other such platinum-ore components as refuse to dissolve in aqua regia. The action of the gas is greatly facilitated by the presence of fixed alkaline chloride.

Polycene Oxides and Salts.

Monoxides have been produced from platinum, palladium, ruthenium, and osmium. PtO and PdO are decided, the other two are very feeble bases.

Sesquioxides, Me_2O_3 , have been got from rhodium, iridium, ruthenium, and osmium. All are basic.

Binoxides, MeO_2 , exist from all the metals except rhodium. PdO_2 , like PtO_2 (see above), is basic or feebly acid; IrO_2 is a feeble base; RuO_2 and OsO_2 are neutral.

Tetroxides, MeO_4 , are formed by osmium and ruthenium only. Both OsO_4 and RuO_4 are easily fusible and very volatile solids. Their vapours have a most powerful smell and are most dangerously poisonous.

Trioxides and *Heptoxides* do not exist as substances; but the groups RuO_3 , OsO_3 , and R_2O_7 unite with alkalis into soluble salts analogous to chromates and permanganates in their constitution respectively. The oxides MeO , Me_2O_3 , MeO_2 are as a rule preparable by evaporating a solution of the respective chloride or potassio- &c. chloride to dryness with excess of carbonate of soda, heating the residue to dull redness, and removing the alkaline chloride and excess of carbonate by lixiviation with water. The oxides remain as very dark-coloured powders insoluble in acids. The corresponding hydrates are precipitated from the solutions of the chlorides or potassio- &c. chlorides, on addition of excess of caustic potash or soda and heating. These hydrates of the oxides are soluble in certain aqueous acids with formation of salts, and in this limited sense only the "oxides" can be said to be "bases."

Salts.—Of these the most characteristic and the best known are compounds of certain of their chlorides with alkaline chlorides.

1. The compounds MeCl_3R_2 (chloroplatinates and analogues), formed by all polycene metals, except rhodium, are all crystalline salts, more or less soluble in water but as a rule insoluble or nearly so in alcohol. The acids MeCl_3H_2 , in which Me is not platinum, exist only as unstable solution, which by the action of excess of caustic soda in the heat, if not by the action of a gentle heat alone, are all reduced to lower chlorides; only the platinum compound possesses a higher degree of stability.

2. Chlorides, MeCl_2 , and potassio- &c. chlorides, MeCl_4R_2 , exist only in the platinum and palladium series.

3. Hexachlorides, Me_2Cl_6 , and compounds thereof with other chlorides are formed only by rhodium, iridium, and ruthenium.

Preparation of the Rarer Polycene Metals.

For this the residues obtained in the industrial extraction of platinum from the ore form the natural raw material. These residues are two in number,—(1) that part of the ore which resisted the action of aqua regia (we will call it the osmiridium residue), and (2) the filtrate from the chloroplatinate of ammonia.

1. Part of the osmiridium in the first residue consists of scales or grains so hard that they cannot be powdered even in a steel mortar. They must be reduced to a fine powder, which is best done by fusing them up with eight to ten parts of zinc and then driving off the "solvent" in a wind-furnace. The osmiridium remains as a dark friable mass, which is easily powdered and incorporated with the originally sifted-off part. The disintegration of the residue may then be effected, according to Wöhler, by mixing it with its own weight of common salt and exposing the mixture to a current of chlorine at a dull red heat within a combustion tube. If the chlorine is moist much of the osmium goes off as vapour of tetroxide, which must be collected in solution of caustic potash. After complete chlorination the contents of the tube are treated with water, when as a rule some undisintegrated osmiridium remains which is filtered off. The solution is mixed with nitric acid and distilled as long as any osmic tetroxide vapours are going off, which are readily recognized by their powerful pungent smell, and of course must be carefully collected in caustic potash ley. The residual liquor (which contains the iridium as IrCl_3Na_2) is supersaturated with carbonate of soda, and evaporated to dryness,

the residue kept at a dull red heat and then lixiviated with water. Alkaliferous oxide of iridium, Ir_2O_3 , remains as a blue-black powder, which needs only be heated in hydrogen to be reduced to metal, from which the alkali is now easily removed by washing with water. Such iridium is always contaminated with more or less osmium, ruthenium, rhodium, and platinum, to remove which the crude metal is fused up with ten parts of lead, and the alloy treated with dilute nitric acid to dissolve the bulk of the lead, when the polyxene metals remain in the shape of a black powder. From this the platinum is extracted by prolonged treatment with dilute aqua regia, and from the residue the rhodium by fusion with bisulphate of potash and subsequent treatment with water, which dissolves away the sulphate of rhodium formed. The residue now left is fused in a gold crucible with ten parts of caustic and three of nitrate of potash, when the ruthenium and osmium assume the form of soluble $\text{MeO}_2\text{K}_2\text{O}$ salts, which are extracted with water and thus removed. What remains is an alkaliferous (blue) sesquioxide of iridium, which as a rule still retains some iron, ruthenium, and traces of gold and silica (G. Matthey). For the final purification of the metal and the recovering of the ruthenium and rhodium see G. Matthey's memoir (*Chem. Soc. Journ.*, 1879, Abstr., p. 772) and chemical handbooks.

The osmium, as already stated, is obtained at an early stage of the process in the shape of a solution of its volatile tetroxide in caustic potash. This solution is mixed with a little alcohol to bring the osmium into the state of osmite, $\text{K}_2\text{O} + \alpha\text{OsO}_2$, which is insoluble in alcohol. This precipitate is digested in sal-ammoniac, to convert it into a yellow compound of the composition $2\text{NH}_4\text{Cl} + \text{OsO}_2(\text{NH}_4)_2$, which latter needs only be heated in hydrogen to be converted into finely divided metallic osmium.

2. The second residue consists of a solution of a variety of polyxene chlorides in sal-ammoniac. This liquor is kept in contact with metallic iron, when the dissolved polyxene metals, and any gold or copper present, come down as a black heavy precipitate. This precipitate includes all the palladium and part of the rhodium as principal components. Bunsen has worked out an exhaustive method for the extracting of all its polyxene metals in pure forms; but it is too complicated to be reproduced here.¹ The customary method for extracting the palladium is to treat the metallic precipitate with aqua regia, which dissolves the palladium and platinum along with some of the iridium and rhodium, to filter, evaporate the residue to a syrup (for bringing the palladium into the form of PdCl_2), redissolve and precipitate the palladium by addition of the exact quantity of mercuric cyanide as cyanide $\text{Pd}(\text{NC})_2$. This cyanide needs only be ignited strongly to leave a residue of metal. But this metal includes at least part of the copper of the original material. To remove it and other impurities, the crude metal is dissolved in hydrochloric acid with the help of free chlorine, and the solution next evaporated to dryness to reduce the PdCl_2H_2 to PdCl_2 . The chloride is redissolved, the solution mixed with enough of ammonia to redissolve the precipitate first produced, and hydrochloric acid gas is now passed into the solution. Yellow palladichloride of ammonium, $\text{PdCl}_2(\text{NH}_4)_2$, is precipitated, while copper and iron remain dissolved. After removal of the mother liquor the double salt is ignited and thus converted into palladium-sponge, which is easily fused up in the oxyhydrogen flame and thus brought into the form of regulus.

Notes on Palladium, Osmium, and Osmiridium.

Palladium, a silver-white metal of great ductility, is much used, notwithstanding its high price, in mechanical dentistry and occasionally also for the graduated limbs of theodolites and other instruments, because, unlike silver, it remains bright in sulphuretted hydrogen.

Of all the properties of this metal the most remarkable is its extraordinary power of "occluding" hydrogen. According to Graham (to whom we owe almost all our knowledge on the subject) the compact metal when immersed in cold hydrogen gas takes up none or at most very little of it; but at higher temperatures very considerable occlusions take place. A certain specimen of foil was found to occlude 526 volumes of the gas at 245°C ., and 643 at 90° to 97°C ., measured at $17\cdot5$ to 18° and one atmosphere's pressure, per unit-volume of metal. The hydrogen, as in the case of platinum, is retained on cooling, and from the cold compound cannot be extracted by means of an absolute vacuum, which re-extracts the gas at a red heat.

Far more striking results can be obtained by using palladium as a negative pole in the electrolysis of (acidulated) water. The coefficient of occlusion then assumes very high values; in Graham's hands it attained its maximum when the palladium was produced electrolytically from a 1·6 per cent. solution of its chloride, and thus hydrogenized while itself in the nascent state. The galvanically deposited sheet was found to contain 982 volumes of hydrogen (measured cold) per unit-volume of original metal, corresponding

approximately to the formula Pd_4H_2 for the compound. When palladium unites with (nascent or free) hydrogen it suffers a very appreciable expansion which on the removal of the hydrogen is followed by a contraction beyond the original volume of the plain metal. This can be most beautifully illustrated by electrolyzing water in an apparatus in which the negative electrode consists of a long strip of palladium-foil of which one side is covered over with varnish or electrolytically deposited platinum. The hydrogen goes in at the bare side of the electrode; this side consequently expands more strongly than the other and the originally straight strip of metal becomes curved. When the current is reversed, hydrogen bubbles at once rise from what is now the negative pole, but the oxygen due at the palladium plate is for a time taken up by the hydrogen occluded there; this hydrogen is gradually consumed, and as it diminishes the plate unbends more and more completely and at last gets bent over in the opposite sense. Palladium by being hydrogenized does not lose any of its metallic properties, but (in the case of complete saturation) its density sinks from 12·38 to 11·79, its tenacity to 82 per cent. of its original value, its electric conductivity in the ratio of 8·1 to 5·9.

Graham views hydrogenized palladium as a true alloy, containing its hydrogen in the form of a metal "hydrogenium." He found that certain palladium alloys take up hydrogen as readily (though less abundantly) as the pure metal does with corresponding expansion, but when dehydrogenized shrink back into exactly their original volume. He calculated that the density of hydrogenium lies somewhere about the value 0·733 (water=1),—which of course means only that the weight of the occluded hydrogen, measured by the weight of a volume of water equal to the expansion observed, is = 0·733. Dewar arrived at 0·620 as being probably nearer the truth, and for the specific heat of hydrogenium found values from 3·79 to 5·88.

Osmium.—According to Deville and Debray, powdery osmium is most readily obtained by mixing the vapour of the tetroxide with that gas ($\text{CO} + \text{CO}_2$) which is prepared by the decomposition of oxalic acid with oil of vitriol, and passing the mixture through a red-hot porcelain tube. The powdery metal readily fuses up with 3 or 4 parts of tin into a homogeneous alloy. When this alloy is treated with hydrochloric acid most of the tin dissolves, and the rest of it can be driven off by heating the residue in HCl gas. There remains ultimately pure osmium in the form of blue crystals endowed with a grey to violet reflex, which are hard enough to scratch glass. Their specific gravity is 22·48, so that osmium, besides being the most infusible of metals, is the heaviest of all known bodies.

Osmiridium.—Native osmiridium forms crystalline plate-shaped grains, distinguished by an extraordinary degree of hardness, which certainly exceeds that of hard-tempered steel. Most of the grains are very minute; the larger ones are utilized for making the so-called "diamond points" of gold pens. Osmiridium would lend itself for endless other applications if it were possible to unite the native dust into large compact masses. From a series of articles in the *Chemical News* (Jan. 2, 9, and 16, 1885), by Nelson W. Perry, it would appear that this problem has been solved, in a sense. John Holland, an American pen-maker, starting from the long-known fact that platinum metals readily unite with phosphorus into relatively easily fusible alloys, succeeded in producing a phosphorized osmiridium which can be cast (and pressed while liquid) into thin continuous slabs even harder than the native substance, and susceptible of being wrought into drills, knife-edges, &c.

Statistics.

The production of platinum-ore in Russia was 2327 kilogrammes in 1862, 492 in 1863, 397 in 1864, 2273 in 1865, 1768 in 1867, and 2050 in 1871,—a total in those six years of 9307. The average production of platinum metal, from 1828 to 1845, amounted to 2623·8 kilogrammes per annum. In 1870 it was only 2005·8 kilos, of which about 80 per cent. came from the Ural Mountains.²

The manufacture of platinum utensils is in the hands of a very few firms, of which that of Messrs Johnson, Matthey, & Co. of London is generally understood to be the most important. Even the total amount of metal which passes through these works in the aggregate is difficult of ascertainment, the more so as some of them at least are discounting large reserves of old metal, including more or less of the obsolete coins. According to an approximate estimate which a very competent authority has kindly furnished, the consumption during the last five years fell little short of 100,000 lb troy,³ of which from 75 to 80 per cent. are believed to have passed through the hands of London manufacturers.

The price of the metal during the last ten or twelve years has ranged from four to eight times that of silver. It is very high at present (1885) in consequence of the constantly increasing demand for platinum utensils. (W. D.)

² From Kamarsch and Heeren's *Technisches Wörterbuch*.

³ Equal to 7464 kilogrammes per annum, which is 3·7 times the amount given above for 1870.

PLATO

PLATO, the Athenian philosopher and father of idealism, was born 427 B.C., and lived to the age of eighty. His literary activity may be roughly said to have extended over the first half of the 4th century B.C. His father's name was Ariston, and his mother's family, which claimed descent from Solon, included Critias, one of the thirty tyrants, and other Athenian notables. That throughout his early manhood he was the devoted friend of Socrates, that in middle life he taught those who resorted to him in the grove named of Academus, near the Cephissus, and there founded the first great philosophical school, that (with alleged interruptions) he continued to preside over the Academy until his death, are matters of established fact. It is said by Aristotle that he was at one time intimate with Cratylus the Heraclitean. Beyond this we have no authentic record of his outward life. That his name was at first Aristocles, and was changed to Plato because of the breadth of his shoulders or of his style or of his forehead, that he wrestled well,¹ that he wrote poetry² which he burnt on hearing Socrates, that he fought in three great battles,³ that he had a thin voice, that (as is told of other Greek philosophers) he travelled to Cyrene and conversed with priests in Egypt, are statements of Diogenes Laertius, which rest on more or less uncertain tradition. The express assertion—which this author attributes to Hermodorus—that after the death of Socrates Plato and other Socratics took refuge with Euclides in Megara, has a somewhat stronger claim to authenticity. But the fact cannot be regarded as certain, still less the elaborate inferences which have been drawn from it. The romantic legend of Plato's journeys to Sicily, and of his relations there with the younger Dionysius and the princely but unfortunate Dion, had attained some degree of consistency before the age of Cicero, and at an unknown but probably early time were worked up into the so-called *Epistles* of Plato, now all but universally discredited. Nor is there sufficient ground for supposing, as some have done, that an authentic tradition is perceptible behind the myth. For the details of the story the reader is referred to Grote,⁴ who believed in the genuineness of the *Epistles*.

It is more important than any further balancing of uncertainties to observe the intellectual tendencies of the preceding generation (c. 430–400 B.C.).

The later years of the Peloponnesian War witnessed much mental disturbance and restlessness at Athens. Thoughtful minds looked forward with apprehension and backwards with regret, while even the most thoughtless were stirred into superficial activity. More than at any time since the age of Clisthenes, the city was divided, and a man's foes were often men of his own tribe or deme. Athenian politics were more factious and less significant than ever. Contention in the law-courts and rivalries in the assembly had for many men a more absorbing interest than questions of peace and war. Hereditary traditions had relaxed their hold, and political principles were not yet formulated. Yet there was not less scope on this account for personal ambition, while the progress of democracy, the necessity of conciliating the people, and the apportionment of public offices by lot had a distracting and, to reflecting persons, often a discouraging effect.

¹ See *Laus*, vii. 814 c.

² Some epigrams in the *Anthology* are attributed to him.

³ This is told on the authority of Aristoxenus. But Plato cannot have been at Delium.

⁴ *History of Greece*, c. lxxxiv.; *Plato*, vol. i. c. iii.

For those amongst whom Plato was brought up this effect was aggravated by the sequel of the oligarchical revolution, while, on the other hand, for some years after the restoration of the democracy, a new stimulus had been imparted, which, though of short duration, was universally felt.

The events and circumstances thus briefly summarized appear in two ways to have encouraged the diffusion of ideas. The ambitious seem to have welcomed them as a means of influence, while those who turned from public life were the more stimulated to speculative disputation. However this may have been, it is manifest that before the beginning of the 4th century B.C. the intellectual atmosphere was already charged with a new force, which although essentially one may be differently described, according to the mode of its development, as (1) rhetorical and (2) theoretical and "sophistical." This last word indicates the channel through which the current influences were mostly derived. A new want, in the shape both of interested and of disinterested curiosity, had insensibly created a new profession. Men of various fatherlands, some native Athenians, but more from other parts of Hellas, had set themselves to supplement the deficiencies of ordinary education, and to train men for the requirements of civic life. More or less consciously they based their teachings on the philosophical dogmas of an earlier time, when the speculations of Xenophanes, Heraclitus, or Parmenides had interested only a few "wise men." Those great thoughts were now to be expounded, so that "even cobblers might understand."⁵ The self-appointed teachers found a rich field and abundant harvest among the wealthier youth, to the chagrin of the old-fashioned Athenian, who sighed with Aristophanes for the good old days when men knew less and listened to their elders and obeyed the customs of their fathers. And such distrust was not wholly unfounded. For, amidst much that was graceful and improving, these novel questionings had an influence that, besides being unsettling, was aimless and unreal. A later criticism may discern in them the two great tendencies of naturalism and humanism. But it may be doubted if the sophist was himself aware of the direction of his own thoughts. For, although Prodicus or Hippias could debate a thesis and moralize with effect, they do not appear to have been capable of speculative reasoning. What passed for such was often either verbal quibbling or the pushing to an extreme of some isolated abstract notion. That *prudens questio* which is *dimidium scientiæ* had not yet been put. And yet the hour for putting it concerning human life was fully come. For the sea on which men were drifting was profoundly troubled, and would not sink back into its former calm. Conservative reaction was not less hopeless than the dreams of theorists were mischievously wild. In random talk, with gay, irresponsible energy, the youth were debating problems which have exercised great minds in Europe through all after time.

Men's thoughts had begun to be thus disturbed and Socrates eager when Socrates arose. To understand him is the most necessary preliminary to the study of Plato. In our first authentic knowledge of him he is a man in mature life, attracting the attention of his fellow-citizens no less by his courage as a soldier than by his strange-familiar presence in the Athenian agora. Like the cicada of the trees by the Ilissus, his voice was never silent—except when checked by his divine monitor, or when wrapt, as he some-

⁵ *Theæt.*, 180 D.

times was for hours, in a catalepsy of reverie (see SOCRATES). When he appeared in the market-place about midday, ready to single out his man for questioning, he had already spent some hours in the wrestling-schools, conversing with the youth. This was not, as it appeared to his contemporaries, mere idleness or mental dissipation (*ἀδολοσχία*), but the exercise of his self-chosen profession. There is no reason to doubt the general truth of the assertion which Plato attributes to him in the *Apologia*. He felt a divine vocation to examine himself by questioning other men. Gifted with an iron frame, and having trained himself to have fewer wants than a soldier or a slave, he could devote all his time to this one object, without engaging in remunerative business, or setting hours apart for recreation, since he was indefatigable alike in body and mind. He was really doing for the Athenians, whether they would or no, what the sophist professed to do for his adherents, and what such men as Protagoras and Prodicus had actually done in part. One obvious difference was that he would take no fee. But there was another and more deep-lying difference, which distinguished him not only from the contemporary sophists but from the thinkers of the previous age. This was the Socratic attitude of inquiry.

The sceptical movement had confused men's notions as to the value of ethical ideas.¹ "If 'right' is one thing in Athens and another at Sparta, why strive to follow right rather than expediency? The laws put restraint on Nature, which is prior to them. Then why submit to law?" And the ingenuities of rhetoric had stirred much unmeaning disputation. Every case seemed capable of being argued in opposite ways. Even on the great question of the ultimate constitution of things, the conflicting theories of absolute immutability and eternal change appeared to be equally irrefragable and equally untenable.

Now Socrates first of all maintained imperturbably the simple habits of an ordinary Athenian citizen, observing scrupulously even minute religious customs, entering also unreservedly into the lightest pastimes of his associates, while the plain and strenuous tenor of his own peculiar life remained unaffected. But into all he carried the same irrepressible, insatiable spirit of search, to which nothing human was alien or uninteresting. Taking men and women as he found them, and conversing casually, as it appeared, on the topic which chanced to interest his hearer, he had not gone far before he had unmasked some vain pretence, cut folly to the quick, or raised some doubt of wide significance. And, though he often ended with negation, his negative achievements had a positive aim. For there underlay the process even when most ironical the conviction, not less profound because implicit, that in spite of false appearances, in spite of error, there are realities not undiscoverable, and whatsoever is real is good. His hearers had been confused by contradictory voices,—one crying "All is motion," another "All is rest"; one "The absolute is unattainable," another "The relative alone is real"; some upholding a vague sentiment of traditional right, while some declared for arbitrary convention and some for the "law of nature." Some held that virtue was spontaneous, some that it was due to training, and some paradoxically denied that either vice or falsehood had any meaning. The faith of Socrates, whether instinctive or inspired, remained untroubled by these jarring tones. He did not ask—"Is virtue a reality?" or "Is goodness a delusion?" But, with perfect confidence that there was an answer, he asked himself and others "What is it?" (*τί ἐστὶ*); or, more particularly, as Xenophon testifies, "What is a state? What is a statesman? What is just? What is unjust?"

What is government? What is it to be a ruler of men?" In this form of question, however simple, the originality of Socrates is typified; and by means of it he laid the first stone, not only of the fabric of ethical philosophy, but of scientific method. The secret of his success lay in the combination of a deep sense of human ignorance with a confidence not less deep in the power of reason.

The first result, and, as the Platonic Socrates declares, the only result he had obtained, was the consciousness of knowing nothing. But he who knows that he knows nothing is disposed to seek, and only those who seek will find. And the seeking mind attains, if not to knowledge, yet to a new standard of knowing. So long as results are contradictory, so long as negative instances are successfully applied, the searcher may make progress but is still to seek. For the aim of inquiry is the universal.

Human life and experience the sphere of search; truth and good, regarded as identical, the end of it; universality the test of reality, conversation the method, rational thought the means,—these are the chief notes of the dialectic of Socrates. Applying the native strength of his intelligence directly to the facts of life, he revealed their significance in countless ways, by unthought-of generalizations, by strange analogies, combining what men had not combined, distinguishing what they had not distinguished,—but always with the single aim of rousing them to the search after eternal truth and good.

The spirit which led on towards this unseen goal was not less practical than speculative. Socrates desired not only that men might know, but that they might know and do. Utility is the watchword no less of the Socratic than of the Baconian induction. But Socrates never doubted that if men once know they will also do. His own conscious conviction of the unity of truth and good he believed to be unconsciously the basis of all men's actions. They erred, he thought, from not seeing the good, and not because they would not follow it if seen. This is expressed in the Socratic *dicta*, "Vice is ignorance," "Virtue is knowledge." Men therefore must be brought to see the good and true, and that they may see it they must first be made aware that they do not see.

This lifelong work of Socrates, in which the germs of ethics, psychology, and logic were contained,—after it had been sealed by the death in which he characteristically at once obeyed his countrymen and convinced them of error,—was idealized, developed, dramatized—first embodied and then extended beyond its original scope—in the writings of Plato, which may be described as the literary outcome of the profound impression made by Socrates upon his greatest follower.

These writings (in pursuance of the importance given by Socrates to conversation) are all cast in the form of imaginary dialogue. But in those which are presumably the latest in order of composition this imaginative form interferes but little with the direct expression of the philosopher's own thoughts. The many-coloured veil at first inseparable from the features is gradually worn thinner, and at last becomes almost imperceptible.

Little more will be attempted in the following pages than to give a general outline of these immortal works in the order which is on the whole most probable, omitting those whose claim to authenticity is weakest, and passing lightly over some which, although genuine, are less important than the rest, or have less to do with the main current of Plato's thought.

The Platonic dialogues are not merely the embodiment of the mind of Socrates and of the reflexions of Plato. They are the portrait of the highest intellectual life of Hellas in the time of Plato,—a life but distantly related to

¹ See Caird, *Hegel*, p. 168.

military and political events, and scarcely interrupted by them. Athens appears as the centre of the excitable Hellenic mind, profoundly stirred by the arrival of great sophists,¹ and keenly alive to the questions of Socrates, although in the pages of Plato, even more than in reality, he only "whispers with a few striplings in a corner." For, in the Platonic grouping, the agora, which was the chief scene of action for the real Socrates, retires into the background, and he is principally seen consorting with his chosen companions, who are also friends of Plato, and with the acquaintances whom he makes through them. The scene is narrowed (for the Academy was remote from the bustle of resort, and Plato judged the Hellenic world securely from the vantage-ground of partial retirement)—but the figures are distinct and full of life. In reading the dialogues, we not only breathe the most refined intellectual atmosphere, but are also present witnesses of the urbanity, the freedom, the playfulness, the generous warmth of the "best society" in Athens. For Plato has a numerous repertory of *dramatis personæ*, who stand in various relations to his chief character—the impetuous Chærephon, Apollodorus the inseparable weak brother, old Crito the true-hearted, Phædo the beloved disciple, Simmias and Cebes, who have been with Philolaus, the graceful and ingenuous Phædrus, the petulant Philebus, Theætetus of the philosophic nature, who is cut off in his prime, and the incorrigible Alcibiades; then Plato's own kinsmen—Glaucón the irrepressible in politics, in quarrel, and in love, Adimantus, solid and grave, Critias in his phase of amateur philosopher, and not as what he afterwards became, Charmides, not in fiery manhood, but in his first bloom of diffident youth; and many others who appear as mere acquaintances, but have an interest of their own—the accomplished Agathon, the gay Aristophanes, Eryximachus the all-worthy physician, Meno, light of spirit, Callias, entertainer of sophists, Callicles the wilful man of the world, Cephalus the aged father of Lysias, and Nicias the honoured soldier. All these appear, not as some of them do on the page of history, in sanguinary contention or fierce rivalry, but as peaceful Athenians, in momentary contact with Socrates, whose electric touch now benumbs and now exhilarates, and sometimes goads to frenzy of love or anger. Still more distantly related to him, as it were standing in an outer circle, are the imposing forms of Gorgias and Protagoras, surrounded with the lesser lights of Hippias, Prodicus, and Polus. Thrasymachus, Euthydemus, Dionysodorus hang round like comic masks, adding piquancy to the design. The adversaries Anytus and Meletus are allowed to appear for a moment, but soon vanish. The older philosophers, though Socrates turned away from them, also make their entrance on the Platonic stage. Parmenides with his magnificent depth is made to converse with the imaginary Socrates, who is still quite young. A stranger from Elea plays an important part in some later dialogues, and Timæus the Pythagorean is introduced discoursing of the creation of the world. In these dialogues Socrates is mostly silent; in the *Philebus* he has lost himself in Plato; and in the twelve books of the *Laws*, where an unnamed Athenian is the chief speaker, even the Platonic Socrates finally disappears.

Now, in evolving his philosophy from the Socratic basis, Plato works along three main lines,—the ethical and political, the metaphysical or scientific, and the mystical. All three are often intimately blended, as in the close of *Rep.*, bk. vi., and even where one element is uppermost the others are not wholly suppressed. But this distinction, like that sometimes made in modern philo-

sophy between the good, the true, and the beautiful, is one which, if not unduly pressed, may be usefully borne in mind. Having noted this once for all, we pass to the more detailed consideration of the several dialogues.

I. *Laches*, *Charmides*, *Lysis*.—In this first group Socrates is dealing tentatively with single ethical notions. The result in each case is a confession of ignorance, but the subject has been so handled as to point the way to more fruitful discussions in the future. And suggestions are casually thrown out which anticipate some of the most far-reaching of Plato's subsequent contemplations.

The *Laches* is a vigorous sketch, in which the characters Laches of the soldier, the aged citizen, and the prudent general are well preserved; and Socrates is seen conversing with his elders, although with reference to the treatment of the young. The question raised is the definition of courage; and the humour of the piece consists in showing that three men, all of whom are unquestionably brave, are unable to give an account of bravery, or to decide whether courage is an animal instinct or a mental accomplishment.

Similarly, in the dialogue which bears his name, the Char-temperate Charmides, of whom all testify that (as Aristophanes has it²) he "fills up the gracious mould of modesty," is hopelessly embarrassed when challenged by the Socratic method to put in words his conception of the modesty or temperance which he possesses, and which, as Socrates assures him, is a priceless gift. The *Charmides* contains some hints of Platonic notions, such as that of knowledge as self-consciousness, and of virtue as "doing one's own business."

The graceful little dialogue which bears the name of *Lysis*. *Lysis* ends, like the two former, with a confession of failure. Socrates, Lysis, and Menexenus are all friends, and think highly of friendship, yet after many efforts they are unable to tell "what friendship is." Yet some of the suggestions which are here laid aside are afterwards allowed to reappear. The notion that "what is neither good nor evil loves the good because of the presence of evil" is expanded and emphasized in the *Symposium*. And the conception of an ideal object of friendship, an *αὐτὸ φῖλον* (though rejected as in the criticism of Aristotle by the characteristic *reductio ad infinitum*), is destined to have a wider scope in the history of Platonism.

II. *Protagoras*, *Io*, *Meno*.—The previous dialogues have marked the distinction between unconscious and conscious morality, and have also brought out the Socratic tendency to identify virtue with the knowledge of good. Now, the more strongly it is felt that knowledge is inseparable from virtue the more strange and doubtful appears such unconscious excellence as that of Laches, Charmides, or Lysis. Hence arises the further paradox of Socrates,—“Virtue is not taught, and that which is commonly regarded as virtue springs up spontaneously or is received unconsciously by a kind of inspiration.”

Protagoras, in the dialogue named after him, is the professor of popular, unscientific, self-complacent excellence; while Socrates appears in his life-long search after the ideal knowledge of the best. The two men are naturally at cross purposes. Protagoras contends that virtue is taught by himself and others more or less successfully, and is not one but many. Socrates disputes the possibility of teaching virtue (since all men equally profess it, and even statesmen fail to give it to their sons), but affirms that, if it can be taught, virtue is not many, but one. The discussion, as in the former dialogues, ends inconclusively. But in the course of it Plato vividly sets forth the natural opposition between the empiric and scientific points of view, between a conventional and an

¹ It had been part of the policy of Pericles to draw distinguished foreigners to Athens.

² *Nub.*, 995, τῆς αἰδοῦς μέλλεις τεῖναι ἀναπλήσαι.

intellectual standard. He does full justice to the thesis of Protagoras, and it is not to be supposed that he was contented to remain in the attitude which he has here attributed to Socrates. In his ideal state, where the earlier training of the best citizens is a refinement on the actual Hellenic education, he has to some extent reconciled the conceptions which are here dramatically opposed.

The preparations for the encounter and the description of it include many life-like touches,—such as the eagerness of the young Athenian gentleman to hear the sophist, though he would be ashamed to be thought a sophist himself; the confusion into which the house of Callias has been thrown by the crowd of strangers and by the self-importance of rival professors; the graceful dignity of the man who has been forty years a teacher, the graphic description of the whole scene, the characteristic speeches of Prodicus and Hippias (from which some critics have elicited a theory of their doctrines), and the continued irony with which Socrates bears them all in hand and soothes the great man after disconcerting him.

In the argument there are two points which chiefly deserve notice. (1) Protagoras, in accordance with his relative view of things (which Plato afterwards criticized in the *Theætetus*), claims not to give men principles but to improve them in those virtues which Providence has given in some measure to all civilized men. (2) Socrates in postulating a scientific principle, which he expressly reserves for future consideration, would have it tested by the power of calculating the amount of pleasure. Grote dwells with some complacency on the "utilitarianism" of Socrates in the *Protagoras*. And it is true that a principle of utility is here opposed to conventional sentiment. But this opposition is intended to prepare the way for the wider and deeper contrast between an arbitrary and a scientific standard, or between impressions and conceptions or ideas. And when Plato (in the *Gorgias* and *Philebus*) endeavours to define the art of measurement, which is here anticipated, it is not wonderful that differences here unthought of should come into view, or that the pleasant should be again contradistinguished from the good. In all three dialogues he is equally asserting the supremacy of reason.

**Inspira-
tion.** On the first vision of that transcendental knowledge¹ which is to be the key at once to truth and good, philosophy is apt to lose her balance, and to look with scorn upon "the trivial round, the common task," and the respectable common-places of "ordinary thinking." Yet, as Socrates is reminded by Protagoras, this unconscious wisdom also has a value. And Plato, who, when most ideal, ever strives to keep touch with experience, is fully convinced of the reality of this lower truth, of this unphilosophic virtue. But he is long puzzled how to conceive of it. For, if knowledge is all in all, what are we to make of wisdom and goodness in those who do not know? Protagoras had boldly spoken of honour and right as a direct gift from Zeus, and Socrates, in the *Io* and *Meno*, is represented as adopting an hypothesis of inspiration in order to account for these unaccredited graces of the soul.

Io. Socrates has observed that rhapsodists and even poets have no definite knowledge of the things which they so powerfully represent (comp. *Apol.*, 22; *Phæd.*, 245 A; *Rep.*, iii. 398 A). He brings the rhapsode Io to admit this, and to conclude that he is the inspired medium of a magnetic influence. The Muse is the chief magnet, and the poet is the first of a series of magnetic rings. Then follow the rhapsode and the actor, who are rings of inferior power, and the last ring is the hearer or spectator.

Meno. The *Meno* raises again the more serious question, Can

virtue be taught? Socrates here states explicitly the paradox with which the *Protagoras* ended. "Virtue is knowledge; therefore virtue can be taught. But virtue is not taught. Therefore (in the highest sense) there can be no virtue." And he repeats several of his former reasons,—that Athenian statesmen failed to teach their sons, and that the education given by sophists is unsatisfying. (The sophists are here denounced by Anytus, who is angered by Socrates's ironical praise of them.) But the paradox is softened in two ways:—(1) the absence of knowledge does not preclude inquiry, and (2), though virtue cannot be taught, yet there is a sense in which virtue exists.

1. Meno begins in gaiety of heart to define virtue, but is soon "benumbed" by the "torpedo" shock of Socrates, and asks "How can one inquire about that which he does not know?" Socrates meets this "eristic" difficulty with the doctrine of reminiscence (*ἀνάμνησις*). All knowledge is latent in the mind from birth and through kindred (or association) of ideas much may be recovered, if only a beginning is made. Pindar and other poets have said that the soul is immortal and that she has passed through many previous states.² And Socrates now gives a practical illustration of the truth that knowledge is evolved from ignorance. He elicits, from a Greek slave of Meno's, the demonstration of a geometrical theorem.³ About the middle of the process he turns to Meno and observes that the slave (who has made a false start) is now becoming conscious of ignorance. He then gradually draws from the man, by leading questions, the positive proof.

2. Though virtue is not yet defined, it may be affirmed "hypothetically" that, if virtue is knowledge, virtue can be taught. And experience leads us to admit two phases of virtue—the one a mode of life based on scientific principle, which hitherto is an ideal only; the other sporadic, springing of itself, yet of divine origin, relying upon true opinion, which it is, however, unable to make fast through demonstration of the cause or reason. But, if there were a virtuous man who could teach virtue, he would stand amongst his fellows like Tiresias amongst the shades.⁴

This mystical account of ordinary morality is in keeping with the semi-mythical defence of the process of inquiry—that all knowledge is implicit in the mind from birth.

III. *Euthyphro*, *Apologia*, *Crito*, *Phædo*.—There is no ground for supposing that these four dialogues were written consecutively, or that they belong strictly to the same period of Plato's industry. But they are linked together for the reader by their common reference to the trial and death of Socrates; no one of them has been proved to be in the author's earliest or latest manner; and they may therefore fitly end the series of dialogues in which the personal traits of the historic Socrates are most apparent, and Plato's own peculiar doctrines are as yet but partially disclosed.

The little dialogue known by the name of *Euthyphro* **Euthyphro.** might have been classed with the *Laches*, *Charmides*, and *Phro.* *Lysis*, as dealing inconclusively with a single notion. But, although slight and tentative in form, it has an undertone of deeper significance, in keeping with the gravity of the occasion. Plato implies that Socrates had thought more deeply on the nature of piety than his accusers had, and also that his piety was of a higher mood than that of ordinary religious men.

Euthyphro is a soothsayer, well-disposed to Socrates, but not one of his particular friends. They meet at the

² The origin of this traditional belief is very obscure. The Greeks themselves were apt to associate it with Pythagoras and with the "Orphic" mysteries.

³ *Euchl.*, i. 47 (the case where the triangle is isosceles).

⁴ *Hom.*, *Odys.*, x. 495, *Οἴφ' πεπνυσθαι, ταὶ δὲ σκαὶ ἀίσσανται*.

¹ *Phæd.*, 82 B; *Rep.*, x. 619 C.

door of the king archon, whither Socrates has been summoned for the "precognition" (*ἀνάκρισις*) preliminary to his trial. Both men are interested in cases of alleged impiety. For Euthyphro's business is to impeach his father, who has inadvertently caused the death of a criminal labourer. The prophet feels the duty of purging the stain of blood to be more imperative the nearer home. Socrates is struck by the strong opinion thus evinced respecting the nature of piety, and detains Euthyphro at the entrance of the court, that he may learn from so clear an authority "what piety is," and so be fortified against Meletus. He leads his respondent from point to point, until the doubt is raised whether God loves holiness because it is holy, or it is holy because loved by God. Does God will what is righteous, or is that righteous which is willed by God? Here they find themselves wandering round and round. Socrates proves himself an involuntary Dædalus who makes opinions move, while he seeks for one which he can "bind fast with reason."

"The holy is a portion of the just." But what portion? "Due service of the gods by prayer and sacrifice." But how does this affect the gods? "It pleases them." Again we are found to be reasoning in a circle.

"Thus far has Socrates proceeded in placing religion on a moral foundation. He is seeking to realize the harmony of religion and morality, which the great poets Æschylus, Sophocles, and Pindar had unconsciously anticipated, and which is the universal want of all men. To this the soothsayer adds the ceremonial element, 'attending upon the gods.' When further interrogated by Socrates as to the nature of this 'attention to the gods,' he replies that piety is an affair of business, a science of giving and asking and the like. Socrates points out the anthropomorphism of these notions. But when we expect him to go on and show that the true service of the gods is the service of the spirit and co-operation with them in all things true and good, he stops short; this was a lesson which the soothsayer could not have been made to understand, and which every one must learn for himself."¹

Apology.

In Plato's *Apology* the fate of Socrates is no longer the subject of mere allusions, such as the rage of Anytus at the end of the *Meno*, and the scene and occasion of the *Euthyphro*. He is now seen face to face with his accusers, and with his countrymen who are condemning him to death.

What most aggravated his danger (after life-long impunity) is thus stated by Mr James Riddell, in the introduction to his edition of the dialogue:—"The *ἐπιείκεια*" (clemency) "of the restored people did not last long, and was naturally succeeded by a sensitive and fanatical zeal for their revived political institutions. Inquiry into the foundations of civil society was obviously rather perilous for the inquirer at such a time. Socrates knew the full extent of his danger. But, according to Xenophon (*Mem.*, iv. c. 8, § 14), he prepared no defence, alleging that his whole life had been a preparation for that hour."

The tone of the Platonic *Apology* is in full accordance with that saying; but it is too elaborate a work of art to be taken literally as a report of what was actually said. Professor Jowett well compares it to "those speeches of Thucydides in which he has embodied his conception of the lofty character and policy of the great Pericles." Yet "it is significant that Plato is said to have been present at the defence, as he is also said to have been absent at the last scene of the *Phædo*. Some of the topics may have been actually used by Socrates, and the recollection of his very words may have rung in the ears of his disciple."

The Platonic *Apology* is in three parts:—(1) before conviction, (2) after conviction and before sentence, (3) after the sentence.

1. Socrates cares not for acquittal. But he does care to explain his life. And he selects those aspects of it which there is hope of making his audience understand. That he partly succeeded in this is shown by the large number of those (220 out of 500) who voted for his acquittal.

a. His answer to Meletus, as least important, is reserved for the middle of his speech. He addresses himself first to "other accusers,"—comic poets and the rest, who have prejudiced his reputation by falsely identifying him with the physical philosophers and the sophists. But what then is the strange pursuit which has given to Socrates the name of wise? It is the practice of cross-examining, to which he was first impelled by the oracle at Delphi, and which he has followed ever since as a religious mission. The god said "Socrates is wise," when he was conscious of no wisdom great or small. So he went in search of some one wiser than himself, but could find none, though he found many who had conceit of wisdom. And he inferred that the god must mean "He is wisest who, like Socrates, is most aware of his own ignorance." This unceasing quest has left him in great poverty, and has made him enemies, who are represented by Anytus, Meletus, and Lycon. And their enmity is further embittered by the pleasure which young men take in seeing pretence unmasked, and in imitating the process of refutation. Hence has arisen the false charge that Socrates is a corrupter of youth.

b. Here he turns to Meletus. "If I corrupt the youth, who does them good?" *Meletus*. "The laws, the judges, the audience, the Athenians generally" (comp. *Protagoras* and *Meno*). "Strange, that here only should be one to corrupt and many to improve; or that any one should be so infatuated as to wish to have bad neighbours." *Meletus*. "Socrates is an atheist. He believes the sun to be a stone." "You are accusing Anaxagoras. I have said that I know nothing of such theories. And you accuse me of introducing novel notions about divine things. How can I believe in divine things (*δαίμνια*) and not in divine beings (*δαίμονες*)? and how in divine beings, if not in gods who are their authors?"

c. That is a sufficient answer for his present accuser. He returns to the general long-standing defamation, which may well be his death, as slander has often been and again will be the death of many a man.

Yet if spared he will continue the same course of life, in spite of the danger. As at Potidæa and Delium he faced death where the Athenians posted him, so now he will remain at the post where he is stationed by the god. For to fear death is to assume pretended knowledge.

One thing is certain. A worse man cannot harm a better. But if the Athenians kill Socrates, they will harm themselves. For they will lose the stimulus of his exhortations;—and his poverty is a sufficient witness that he was sincere. Not that he would engage in politics. If he had done that he would have perished long before,² as he nearly did for his independent vote after the battle of Arginusæ, and for disobeying the murderous command of the thirty tyrants.

But have not Socrates's disciples, Alcibiades, Critias, Charmides, proved bad citizens? He has no disciples. Any one, bad or good, may come and hear him, and the talk which is his life-work is not unamusing. But why are no witnesses brought to substantiate this charge? There are elder friends of his companions, who would be angry if he had used his influence for harm. But these men's confidence in Socrates is unshaken.

He will not appeal *ad misericordiam*. That would be a disgrace for one who (rightly or not) has been reputed wise, and to admit such an appeal in any case is a violation of the juror's oath.

Socrates has told the Athenians the whole truth, so far as a mixed audience of them could receive it. Elaboration and subtlety could have no place in addressing the Heliastic court, nor could that universal truth towards which he was leading men be made intelligible to a new audience while the clepsydra was running. But his tone and attitude must have made a strong appeal to the better nature of his hearers. With Meletus he "played rather than fought," but he has shown clearly that he has no fear of death, that he chooses to obey God rather than man, and that for very love of the Athenians he will not be swayed by their desires.

2. One convicted on a capital charge had the right of pleading before sentence in mitigation of the penalty proposed by his accuser. Socrates was convicted by fewer votes than he himself anticipated. The indictment of Meletus was ineffectual, and if it had not been for the speeches of Anytus and Lycon the defendant would have been triumphantly acquitted. Could he but have conversed with his judges more than once, he might have removed their prejudices. In no spirit of bravado, therefore, but in simple justice to himself, he meets the claim of Meletus that he shall be punished with death by the counter claim that he shall be maintained in the prytaneum as a public benefactor. He cannot ask that death, which may be a good, shall be commuted for imprisonment or exile, which are certainly evils. A fine would be no evil: but he has no money;—he can offer a mina. Here Plato and others interpose, and with their friendly help he offers thirty minæ.

3. He is sentenced to death, and the public business of the court

¹ Jowett.

² Comp. *Gorg.*, 521; *Rep.*, vi. 496.

is ended. But, while the record is being entered and the magistrates are thus occupied, Socrates is imagined as addressing (a) the majority, and (b) the minority in the court.

a. To those who have condemned him he speaks in a prophetic tone. "For the sake of depriving an old man of the last dregs of life, they have given Athens a bad name. He would not run away, and so death has overtaken him. But his accusers are overtaken by unrighteousness, and must reap the fruits of it.

"Nor will the Athenians find the desired relief. Other reprovers, whom Socrates has hitherto restrained, will now arise, not in a friendly but in a hostile spirit. The only way for the citizens to escape reproof is to reform their lives."

b. To the minority, who would have acquitted him, he speaks with gentle solemnity. "Let them know to their comfort that the divine voice has not once checked him throughout that day. This indicates that death is not an evil. And reason shows that death is either a long untroubled sleep, or removal to a better world, where are no unjust judges.

"No evil can happen to a good man either in life or after death. Wherefore Socrates will not be angry with his condemners, who have done him no harm, although they meant him anything but good. He will only ask of them to do to the sons of Socrates as Socrates has done to them."

Crito.

Is the love of truth consistent with civic duties? Is the philosopher a good citizen? are questions which are sure to arise where the truth involves practical improvement. In the *Apology* Socrates appears as an intrepid reformer; the *Crito* gives an impressive picture of him as a loyal and law-abiding Athenian.

Execution had been delayed during the annual mission to Delos (during which no one could be put to death). But the returning vessel had just been reported as desecrated from Sunium. At early dawn Crito, the oldest friend of Socrates, obtained access to his cell, and found him sleeping peacefully. Presently he awoke, and Crito told him of the approach of the fatal ship. Socrates replies by telling his dream. A fair form stood over him and said,

"The third day hence to Phthia shalt thou come."

And it would seem that the day after to-morrow will really be the day for going home.

Crito then reveals his plan for an escape. And Socrates argues the question in the old familiar way. "Crito's zeal is excellent, and most men would think his object right. But the few who think soundly say that it is wrong to return evil for evil. The laws of Athens (through the fault of men) are doing Socrates harm. But ought he therefore to infringe the law? Might not the laws of his country plead with him and say:—'You owe to us your birth and breeding; and when grown up you voluntarily submitted to us. For you might have gone elsewhere. But you preferred us to all other laws, and have been the most constant resident in Athens. Even at the last you accepted death rather than exile. If you now break your covenant, you will ruin your friends and will be rejected by all well-ordered cities. You might be received in Thessaly, but could only live there by cringing to foreigners for food. Where in that case will be your talk about virtue? You would not take your sons thither. And your friends would be equally kind to them if you were dead.

"Think not of life and children first and of justice afterwards, but think of justice first, that you may be justified in the world below." Crito admits these arguments to be unanswerable.

Phædo.

The *Meno* referred to the immortality and pre-existence of the soul as a traditional doctrine, and it was there associated with the possibility of inquiry. In the *Phædo* Plato undertakes to substantiate this belief and base it anew, by narrating the last hours of Socrates, who is represented as calmly discussing the question with his friends when his own death was immediately at hand. The argument turns chiefly on the eternity of knowledge, and is far from satisfying. For, granting that eternity of knowledge involves eternity of mind, does the eternity of mind assure continued being to the individual?¹ Yet no unprejudiced reader of the *Phædo* can doubt that Plato, at the time of writing it, sincerely believed in a conscious personal existence after death. The words of Socrates, when he declares his hope of going to be with other friends, are absolutely unambiguous, and his reply to Crito's question, "How shall we bury you?" has a convincing

force beyond all dialectic:—"I cannot persuade Crito that I here am Socrates—I who am now reasoning and ordering discourse. He imagines Socrates to be that other, whom he will see by and by, a corpse." This and similar touches not only stamp the *Phædo* as a marvel of art, but are indisputable evidences of the writer's profound belief. They may be inventions, but they have nothing "mythical" about them, any more than the charge of Socrates to his friends, that they would best fulfil his wishes by attending to their own lives.

The narrative, to be appreciated, must be read in full. But a short abstract of the argument may be given here.

1. Death is merely the separation of soul and body. And this is the very consummation at which philosophy aims. The body hinders thought. The mind attains to truth by retiring into herself. Through no bodily sense does she perceive justice, beauty, goodness, and other ideas. The philosopher has a life-long quarrel with bodily desires, and he should welcome the release of his soul. Thus he alone can have true courage, even as temperance and all the virtues are real in him alone.

But does the soul exist after death?

a. An old tradition tells of many successive births, the soul departing to Hades and returning again, so that the living are born from the dead. And if the dead had no existence, this could not be, since from nothing nothing can arise. Moreover, experience shows that opposite states come from their opposites, and that such a process is always reciprocal. Death certainly succeeds to life. Then life must succeed to death. And that which undergoes these changes must exist through all. If the dead came from the living, and not the living from the dead, the universe would ultimately be consumed in death.

This presumption is confirmed by the doctrine (here attributed to Socrates, comp. *Meno*) that knowledge comes through recollection. What is recollected must be previously known. Now we have never since birth had intuition of the absolute equality of which (through association) we are reminded by the sight of things approximately equal. And we cannot have seen it at the moment of birth, for at what other moment can we have forgotten it? Therefore, if ideals be not vain, our souls must have existed before birth, and, according to the doctrine of opposites above stated, will have continued existence after death.

b. To charm away the fears of the "child within," Socrates adds, as further considerations:—

(1) The soul is uncompounded, incorporeal, invisible, and therefore indissoluble and immutable.

(2) The soul commands, the body serves; therefore the soul is akin to the divine.

(3) Yet even the body holds together long after death, and the bones are all but indestructible.

The soul, if pure, departs to the invisible world, but, if tainted by communion with the body, she lingers hovering near the earth, and is afterwards born into the likeness of some lower form. That which true philosophy has purified alone rises ultimately to the gods. This lesson is impressively applied.

2. A pause ensues; and Simmias and Cebes are invited to express their doubts. For, as the swan dies singing, Socrates would die discoursing.

a. Simmias desires not to rest short of demonstration, though he is willing to make the highest attainable probability the guide of life.

If the soul is the harmony of the body, what becomes of her "when the lute is broken"?

b. Cebes compares the body to a garment which the soul keeps weaving at. The garment in which the weaver dies outlasts him. So the soul may have woven and worn many bodies in one lifetime, yet may perish and leave a body behind. Or even supposing her to have many lives, does even this hypothesis exempt her from ultimate decay?

Socrates warns his friends against losing faith in inquiry. Theories, like men, are disappointing; yet we should be neither misanthropists nor misologists. Then he answers his two friends.

(a) (1) The soul is acknowledged to be prior to the body. But no harmony is prior to the elements which are harmonized.

(2) The soul has virtue and vice, i.e., harmony and discord. Is there harmony of harmony? Comp. *Rep.*, x. 609.

(3) All soul is equally soul, but all harmony is not equally harmonious.

(4) If the soul were the harmony of the body, they would be agreed; but, as has been already shown, they are perpetually quarrelling.

(5) The soul is not conditioned by the bodily elements, but has the power of controlling them.

(b.) Cebes has raised the wide question whether the soul is independent of generation and corruption. Socrates owns that he him-

¹ In the *Timæus* immortality is made to rest on the goodwill of God, because "only an evil being would wish to dissolve that which is harmonious and happy" (*Tim.*, 41 A).

self (i.e., Plato?) had once been fascinated by natural philosophy, and had sought to give a physical account of everything. Then, hearing out of Anaxagoras that mind was the disposer of all, he had hoped to learn not only how things were, but also why. But he found Anaxagoras forsaking his own first principle and jumbling causes with conditions. ("The cause why Socrates sits here is not a certain disposition of joints and sinews, but that he has thought best to undergo his sentence,—else the joints and sinews would have been ere this, by Crito's advice, on the way to Thessaly.") Physical science never thinks of a power which orders everything for good, but expects to find another Atlas to sustain the world more strong and lasting than the reason of the best.

Socrates had turned from such philosophers and found for himself a way, not to gaze directly on the universal reason, but to seek an image of it in the world of mind, wherein are reflected the ideas, as, for example, the idea of beauty, through partaking of which beautiful things are beautiful. Assuming the existence of the ideas, he felt his way from hypothesis to hypothesis.

Now the participation of objects in ideas is in some cases essential and inseparable. Snow is essentially cold, fire hot, three odd, two even. And things thus essentially opposite are exclusive of each other's attributes. (When it was said above that opposites come from opposites, not opposite things were meant, but opposite states or conditions of one thing.) Snow cannot admit heat, nor fire cold; for they are inseparable vehicles of heat and cold respectively. The soul is the inseparable vehicle of life, and therefore, by parity of reasoning, the soul cannot admit of death, but is immortal and imperishable.

3. What follows is in the true sense *mythological*, and is admitted by Socrates to be uncertain.—"Howbeit, since the soul is proved to be immortal, men ought to charm their spirits with such tales."

The earth, a globe self-balanced in the midst of space, has many mansions for the soul,¹ some higher and brighter, some lower and darker than our present habitation. We who dwell about the Mediterranean Sea are like frogs at the bottom of a pool. In some higher place, under the true heaven, our souls may dwell hereafter, and see not only colours and forms in their ideal purity but truth and justice as they are.

In the *Phædo*, more than elsewhere, Plato preaches withdrawal from the world. The Delian solemnity is to Socrates and his friends a period of "retreat," in which their eyes are turned from earthly things to dwell on the eternal. The theory of ideas here assumes its most transcendental aspect, and it is from portions of this dialogue and of the *Phædrus* and *Timæus* that the popular conception of Platonism has been principally derived. But to understand Plato rightly it is not enough to study isolated passages which happen to charm the imagination; nor should single expressions be interpreted without regard to the manner in which he presents the truth elsewhere.

It has already been shown (1) that Socratic inquiry implied a standard of truth and good, undiscovered but endlessly discoverable, and to be approached inductively; and (2) that in Plato this implicit assumption becomes explicit, in the identification of virtue with knowledge (*Lach.*, *Charm.*) as an art of measurement (*Protag.*), and in the vision (towards the end of the *Lysis*) of an absolute object of desire. The Socratic "self-knowledge" has been developed (*Charm.*) into a science of mind or consciousness, apart from which no physical studies can be fruitful. (3) Co-ordinate with these theoretical tendencies there has appeared in Plato the determination not to break with experience.—The bearing of these remarks on the further progress of Plato's thoughts will appear in the sequel. Meanwhile, in the *Phædo*, a long step is made in the direction of pure idealism. The ordinary virtue, which in the *Protagoras* and *Meno* was questioned but not condemned, is here rejected as unreal, and the task proposed to the philosopher is less to understand the world than to escape from it. The universal has assumed the form of the ideal, which is supposed, as elsewhere in Plato, to include

mathematical as well as moral notions. The only function of perception is to awaken in us some reminiscence of this ideal. By following the clue thus given, and by searching for clearer images of truth in the world of mind, we may hope to be emancipated from sensation, and to lay hold upon the sole object of pure reason.

It is obvious that when he wrote the *Phædo* Plato conceived of universals as objective entities rather than as forms of thought. The notion of "ideal colours" (though occurring in the myth) is an indication of his ontological mood.

Yet even here the *εἶδη* are not consistently hypostatized. The notion of "what is best" has a distinctly practical side, and the "knowledge through reminiscence" is in one aspect a process of reflexion on experience, turning on the laws of association.² It is also said that objects "partake" of the ideas, and some concrete natures are regarded as embodiments or vehicles of some of them. Still, if taken as a whole, notwithstanding the scientific attitude of Socrates, the *Phædo* is rather a meditation than an inquiry,—a study of the soul as self-existent, and of the mind and truth as co-eternal.

IV. *Symposium*, *Phædrus*, *Cratylus*.—Socrates is again imagined as in the fulness of life. But the real Socrates is becoming more and more inextricably blended with Platonic thought and fancy. In the *Apology* there is a distinct echo of the voice of Socrates; the *Phædo* gives many personal traits of him; but the dialogues which are now to follow are replete with original invention, based in part, no doubt, on personal recollections.

The *Symposium* admits both of comparison and of contrast with the *Phædo*. Both dialogues are mystical, both are spiritual, but the spirituality in either is of a different order. That is here immanent which was there transcendent; the beautiful takes the place of the good. The world is not now to be annihilated, but rather transfigured, until particular objects are lost in universal light. Instead of flying from the region of growth and decay, the mind, through intercourse with beauty, is now the active cause of production. Yet the life of contemplation is still the highest life, and philosophy the truest *μουσική*.

The leading conception of the *Symposium* has been anticipated in the *Lysis*, where it was said that "the indifferent loves the good, because of the presence of evil."

The banqueters (including Socrates), who are met to celebrate the tragic victory of Agathon, happen not to be disposed for hard drinking. They send away the flute-girl and entertain each other with the praise of Love.

Phædrus tells how Love inspires to honourable deeds, and how Alcestis and Achilles died for Love.

Pausanias rhetorically distinguishes the earthly from the heavenly Love.

The physician Eryximachus, admitting the distinction, yet holds that Love pervades all nature, and that art consists in following the higher Love in each particular sphere. So Empedocles had spoken of Love as overcoming previous discord. For opposites cannot, as Heraclitus fancied, coexist.

Aristophanes, in a comic myth, describes the origin of Love as an imperfect creature's longing for completion. The original double human beings were growing impious, and Zeus split them in twain, ever since which act the bereaved halves wander in search of one another.

Agathon speaks, or rather sings, of Love and his works. He is the youngest, not the eldest of gods, living and moving delicately wherever bloom is and in the hearts of men,—the author of all virtue and of all good works, obeyed by gods, fair and causing all things fair, making men to be of one mind at feasts—plot, defender, saviour, in whose footsteps all should follow, chanting strains of love.

Socrates will not attempt to rival the poet, and begins by stipulating that he may tell the truth. He accepts the distinction between Love and his works, but points out that, since desire implies want, and the desire of Love is toward beauty, Love, as wanting beauty, is not beautiful. So much being established in

¹ Comp. Milton, *Il Penseroso*, 88-92—

"To unsphere
The spirit of Plato, to unfold
What worlds or what vast regions hold
The immortal mind that hath forsook
Her mansion in this fleshly nook."

² Comp. *Theæt.*, 184-186.

the Socratic manner, he proceeds to unfold the mystery once revealed to him by Diotima, the Mantinean wise woman.

Love is neither beautiful nor ugly, neither wise nor foolish, neither god nor mortal. Between gods and mortals is the world of mediating spirits (*τὰ δαιμόνια*). And Love is a great spirit, child of Resource (the son of Prudence) and Poverty the beggar maid, who conceived him at the birthday feast of Aphrodite. He is far from living "delicately," but is ragged and shoeless, always in difficulties, yet always brimming with invention, a mighty hunter after wisdom and all things fair; sometimes "all full with feasting" on them, the next moment "clean starved" for lack; never absolutely knowing nor quite ignorant. That is to say, he is a "philosopher." For knowledge is the most beautiful thing, and love is of the beautiful.

But what does love desire of the beautiful? The possession is enough. But there is one kind of love—called "being in love"—which desires beauty for a peculiar end. The lover is seeking, not his "other half," but possession of the beautiful and *birth in beauty*.

For there is a season of puberty both in body and mind, when human nature longs to create, and it cannot save in presence of beauty. This yearning is the earnest of immortality. Even in the bird's devotion to its mate and to its young there is a craving after continued being. In individual lives there is a flux, not only of the body, but in the mind. Nay, the sciences themselves also come and go (here the contrast to the *Phædo* is at its height). But in mortal things the shadow of continuity is succession.

The love of fame is a somewhat brighter image of immortality than the love of offspring. Creative souls would bring into being not children of their body, but good deeds. And such a one is readiest to fall in love with a fair mind in a fair body, and then is filled with enthusiasm and begets noble thoughts. Homer, Hesiod, Lycurgus, Solon, were such genial minds. But they stopped at the threshold (comp. *Prot.*, *Meno*), and saw not the higher mysteries, which are reserved for those who rise from noble actions, institutions, laws, to universal beauty. The true order is to advance from one to all fair forms, then to fair practices, fair thoughts, and lastly to the single thought of absolute beauty. In that communion only, beholding beauty with the eye of the mind, one shall bring forth realities and become the friend of God and be immortal, if mortal man may.

Alcibiades here breaks in and is vociferously welcomed. He is crowning Agathon, when, on perceiving Socrates, he declares that he will crown him too. Then he announces himself king of the feast, and insists upon hard drinking (though this will make no difference to Socrates).

Eryximachus demands from the newcomer a speech in praise of love. But Alcibiades will praise no one else when Socrates is near. And with the freedom of one who is deep in wine he proceeds with his strange encomium of "this Marsyas."

"In face and outward bearing he is like a Satyr or Silenus, and by his voice he charms more powerfully than they do by their pipings. The eloquence of Pericles has no effect in comparison with his. His words alone move Alcibiades to shame, and fascinate him until he stops his ears and runs from him."—"I often wish him dead. Yet that would break my heart. He brings me to my wit's end."—"And, as carved Sileni are made to encase images of gods, so this Silenus-mask entreasures things divine. He affects ignorance and susceptibility to beauty. Thus he mocks mankind. But he cares nothing for outward shows, and his temperance (*σωφροσύνη*) is wonderful."

To prove this Alcibiades reveals his own heart-secret. (He is not ashamed to speak it amongst others who have felt the pang which Socrates inflicts.) And he makes it abundantly manifest that in their widely-rumoured intercourse (comp. *Protag.* init.) Socrates had never cared for anything but what was best for his younger friend. Alcibiades then relates as an eyewitness the endurance shown by Socrates at Potidea, his strange persistence in solitary meditation,—standing absorbed in thought for a day and a night together,—and his intrepid conduct in the retreat from Delium (comp. *Laches*). "The talk of Socrates is of pack-asses and cobblers, and he is ever saying the same things in the same words; but one who lifts the mask and looks within will find that no other words have meaning." Alcibiades ends by warning his companions against the wiles of Socrates.

Some raillery follows, and they are invaded by another band of revellers, who compel them to drink still more deeply. The soberly inclined (led by Eryximachus) slink off, and Aristodemus, the reporter of the scene, only remembers further that when he awoke at cock-crow Socrates was still conversing with Agathon and Aristophanes, and showing them that tragedy and comedy were essentially one. He talked them both asleep, and at daybreak went about his usual business.

The philosopher of the *Symposium* is in the world and yet not of it, apparently yielding but really overcoming. In the *Phædo* the soul was exhorted to "live upon her servant's loss," as in Shakspeare's most religious sonnet;

this dialogue tells of a "soul within sense" in the spirit of some more recent poetry. By force of imagination rather than of reason, the reconciliation of becoming (*γένεσις*) with being (*οὐσία*), of the temporal with the eternal, is anticipated. But through the bright haze of fancy and behind the mask of irony, Socrates still appears the same strong, pure, upright, and beneficent human being as in the *Apology*, *Crito*, and *Phædo*.

The impassioned contemplation of the beautiful is again *Phædrus*. imagined as the beginning of philosophy. But the "limitless ocean of beauty" is replaced by a world of supramundane forms, beheld by unembodied souls, and remembered here on earth through enthusiasm, proceeding by dialectic from multiform impressions to one rational conception, and distinguishing the "lines and veins" of truth. The *Phædrus* records Plato's highest "hour of insight," when he willed the various tasks hereafter to be fulfilled. In it he soars to a pitch of contemplation from whence he takes a comprehensive and keen-eyed survey of the country to be explored, marking off the blind alleys and paths that lead astray, laying down the main lines and chief branches, and taking note of the erroneous wanderings of others. Reversing the vulgar adage, he flies that he may creep.

The transcendent aspiration of the *Phædo* and the mystic glow of the *Symposium* are here combined with the notion of a scientific process. No longer asking, as in the *Protagoras*, Is virtue one or many? Plato rises to the conception of a scientific one and many, to be contemplated through dialectic,—no barren abstraction, but a method of classification according to nature.

This method is to be applied especially to psychology, not merely with a speculative, but also with a practical aim. For the "birth in beauty" of the *Symposium* is here developed into an art of education, of which the true rhetoric is but the means, and true statesmanship an accidental outcome.

Like all imaginative critics, Plato falls to some extent under the influence of that which he criticizes. The art of rhetoric which he so often travestied had a lasting effect upon his style. Readers of his latest works are often reminded of the mock grandiloquence of the *Phædrus*. But in this dialogue the poetical side of his genius is at the height. Not only can he express or imitate anything, and produce any effect at will, but he is standing behind his creation and disposing it with the most perfect mastery, preserving unity amidst profuse variety, and giving harmony to a wildness bordering on the grotesque.

The person of Socrates is here deliberately modified. He no longer (as in the *Symposium*) teaches positive wisdom under the pretence of repeating what he has heard, but is himself caught by an exceptional inspiration, which is accounted for by the unusual circumstance of his finding himself in the country and alone with *Phædrus*. He has been hitherto a stranger to the woods and fields, which would tempt him away from studying himself through intercourse with men. But by the promise of discourse—especially of talk with *Phædrus*—he may be drawn anywhere.

Phædrus has been charmed by a discourse of Lysias, which after some coy excuses he consents to read.

It is a frigid erotic diatribe, in which one not in love pleads for preference over the lover. Socrates hints at criticism, and is challenged to produce something better on the same theme.

1. Distinguishing desire from true opinion, he defines love as desire prevailing against truth, and then expatiates on the harmful tendencies of love as so defined. But he becomes alarmed at his own unwonted eloquence, and is about to remove, when the "divine token" warns him that he must first recite a "palinode" in praise of love. For no divine power can be the cause of evil.

2. Love is madness; but there is a noble madness, as is shown by soothsayers (called *μάντρες* from *μανθάναι*). And of the higher madness there are four kinds.

To explain this it is necessary to understand psychology. The soul is self-existent and self-moving, and therefore eternal. And her form is like a pair of winged steeds with their charioteer. In divine souls both steeds are good, but in human souls one of them is bad. Now before entering the body the soul lost her wings, which in her unembodied state were nourished by beauty, wisdom, goodness, and all that is divine. For at the festival of souls, in which they visit the heaven that is above the heavens, the unruly steed caused the charioteer to see imperfectly. So the soul cast her feathers and fell down and passed into the human form. And, according to the comparative clearness or dimness of that first vision, her earthly lot is varied from that of a philosopher or artist down through nine grades (including woman) to that of a tyrant. On her conduct in this state of probation depends her condition when again born into the world. And only in ten thousand years can she return to her pristine state, except through a life of philosophy (comp. *Phædo*) or of pure and noble love (comp. *Symposium*).

The mind of the philosopher alone has wings. He is ever being initiated into perfect mysteries, and his soul alone becomes complete. But the vulgar deem him mad and rebuke him; they do not see that he is inspired.

This divine madness (the fourth kind of those above mentioned) is kindled through the renewed vision of beauty. For wisdom is not seen; her loveliness would have been transporting if she had a visible form. The struggle of the higher passion with the lower is then described with extraordinary vividness, under the image of the two steeds. When the higher impulse triumphs, the issue is a philosophic friendship, at once passionate and absolutely pure.

3. From his "palinode" Socrates returns to Lysias, who is advised to leave speech-writing for philosophy.

a. Phædrus remarks that the speech-writer is despised by the politician. Socrates replies that speech-writing and politics are one concern. The real difference is between those who base their teaching on philosophy and those who are content with rules of art. For example, if the first speech of Socrates is compared with that of Lysias, the one is found to distinguish and define, the other not; the one observes order in discourse, the other "begins where he should end," and his utterance is like a disordered chain. A speech should be an organic whole, a "creature having hands and feet." So in the "palinode" there was a classification of the kinds of madness, which led the way to "a possibly true though partly erring myth."

This approximation to truth in the midst of much that was playful was due to the observance of two principles, generalization and division (*συναγωγή, διαίρεσις*). Whoever sees the one and many in nature, him Socrates follows and walks in his footsteps, as if he were a god.

In comparison of dialectic, as thus conceived, the frigid rules of Lysias, Thrasymachus, Theodorus, Euenus, Tisias, Gorgias, Polus, and Protagoras are futile and absurd.

b. Another condition of teaching (or true rhetoric) is the science of mind. Whether the soul be one or many, complex or multiform, and if multiform what are its parts and kinds, are questions which the teacher must have already solved. And he must likewise have classified all arguments and know them in their various applicability to divers souls. An art of speaking that should fulfil this condition is non-existent. Yet how can even verisimilitude be attained without knowledge of truth?

c. The art of writing is kindred to the art of speech. But Socrates maintains that oral teaching through the living contact of mind with mind has many advantages over written composition, which is, comparatively speaking, a dead thing. Men may write for amusement or to record the intercourse that has been. But the serious occupation of the true thinker and teacher is the communication of truth through vital converse with others like-minded,—the creation of "thoughts that breathe" in spirits conscious of their value.

In conclusion, a friendly hint is given to Isocrates that he may do better than Lysias if he will but turn his attention to philosophy.

The *Phædrus* anticipates much that Plato afterwards slowly elaborated, and retains some things which he at last eliminated. (1) The presence of movement or impulse in the highest region is an aspect of truth which reappears in the *Sophistes* and other later dialogues. It has been thought strange that it should be found so early as in the *Phædrus*. But does not this remark imply an unwarrantable assumption, viz., that Plato's idealism took its departure from the being of Parmenides? Is it not rather the fact that his own theory was formulated before the Megarian ascendancy led him to examine the Eleatic doctrine, and that it was by a tendency from the first inherent in Platonism that that doctrine was modified

in his final teaching? (2) The outlines of method which are thrown out at white heat in the *Phædrus* are a preparation for the more sober treatment of the ideas in the dialectical dialogues. In these, however, the conception of classification is somewhat altered through contact with Eleaticism. (3) The *Phædrus* aims, not merely at realizing universals, but at grasping them in and through particulars. This is an ideal of knowledge which was "lost as soon as seen," but one which in some of his latest dialogues, such as the *Politicus* and *Philebus*, Plato again endeavours to work out. (4) The *Phædrus* contains the elements of that true psychology into which the ontological theory of the ideas is gradually transmuted in Plato's more advanced writings, when the difficulties of his ideal doctrine in its cruder forms have been clearly felt and understood. (5) Plato here appears as a professor of education, preferring oral intercourse to authorship. In this paradox he at once exalts the work of Socrates and avows his own vocation as a teacher. The passage throws an interesting light upon the form of dialogue in which his works are cast. But it is not to be supposed that he remained long unconscious of the influence he was destined to wield by writing. In undertaking a great task like the *Republic*, he practically receded from the untenable view asserted here; and in the *Laws* he recommends his longest and most prosaic work as a suitable basis for the education of the future. (6) It must always appear strange, even to those most familiar with the conditions of Hellenic life, that in portraying the idealizing power of passionate love Plato should have taken his departure from unnatural feeling.

On this subject he has sung his own "palinode" in the *Laws*, which he intended as his final legacy to mankind.¹ Not that he ceased to exalt genius and originality above mere talent, or to demand for philosophy the service of the heart as well as the head, nor yet that friendship was less valued by him in later years. All this remained unchanged. And in the *Republic* the passion of love is still distantly referred to as the symbol of ideal aspiration. But a time came when he had learned to frown on the aberration of feeling which in the *Symposium* and *Phædrus* he appears to regard as the legitimate stimulus of intellectual enthusiasm. And already in the *Theætetus* not love but wonder is described as the only beginning of philosophy.

While calling attention to this change of sentiment, it is right to add that Platonic love in the "erotic" dialogues of Plato is very different from what has often been so named, and that nothing even in the noble passage of the *Laws* above referred to casts the slightest shadow of blame on the Socrates of the *Symposium*.

Such changes are, amongst other things, a ground for caution in comparing the two steeds of the *Phædrus* with the spirit (*θυμός*) and desire (*ἐπιθυμία*) of the *Republic* and *Timæus*. The *Phædrus*, in common with these dialogues, asserts the existence of higher and lower impulses in human nature, but there is no sufficient ground for supposing that when Plato wrote the *Phædrus* he would have defined them precisely as they are defined in the *Republic*.

The *Cratylus* is full of curious interest as marking the highest point reached by the "science of language" in antiquity; but, as this dialogue "hardly derives any light from Plato's other writings,"² so neither does it reflect much light on them. It deals slightly with the contrast between Heracliteanism and Eleaticism, the importance of dialectic, the difficulty about the existence of falsehood, and ends with a brief allusion to the doctrine of ideas,—but these topics are all more fully discussed elsewhere.

¹ *Laws*, viii, 836.

² Professor Jowett,—who has, notwithstanding, thrown much light on the *Cratylus* in his brilliant introduction.

Three persons maintain different views respecting the nature and origin of language.

Hermogenes affirms that language is conventional, Cratylus (the Heraclitean) that it is natural. Socrates, mediating between these sophistical extremes, declares that language, like other institutions, is natural, and therefore (1) is based on nature, but (2) modified by convention.

In his dialectical treatment of the subject, Socrates displays a tissue of wild etymologies in reliance on the "inspiration" of Euthyphro. Presently a distinction appears between primary and secondary words. Many primary words convey the notion of movement and change. It follows that the legislator or word-maker held Heraclitean views. Socrates thus far presses on Hermogenes the view of Cratylus. Then turning to Cratylus he asks if there are no false names. "False language," Cratylus argues, "is impossible." Socrates shows that a true image may be inadequate, so that we have a right to criticize the work of the word-maker. And the facts indicate an element of meaningless convention. Nor was the original word-maker consistently Heraclitean. For some important words point not to motion but to rest.

But the question returns—Are we sure that the theory of nature which the word-maker held was true? This difficulty cannot be touched by verbal arguments. In seeking to resolve it we must consider, not words, but things. If there is a true beauty and a true good, which are immutable, and if these are accessible to knowledge, that world of truth can have nothing to do with flux and change.

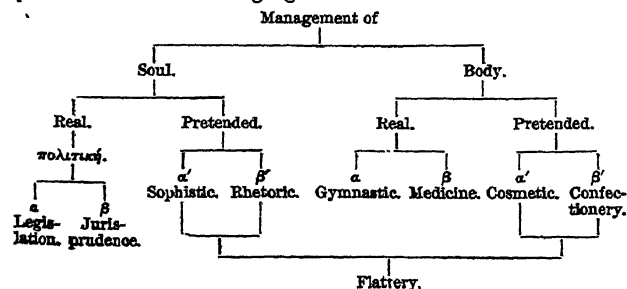

V. *Gorgias, Republic*.—In the *Symposium* and *Phædrus* Plato largely redeems the promise implied in the *Phædo*, where Socrates tells his friends to look among themselves for a charmer who may soothe away the fear of death. But he was pledged also to a sterner duty by the warning of Socrates to the Athenians, in the *Apology*, that after he was gone there would arise others for their reproof, more harsh than he had been. To this graver task, which he had but partially fulfilled with the light satire upon Lysias or the gentle message to Isocrates, the philosopher now directs his powers, by holding up the mirror of what ought to be against what is, the principles of truth and right against the practice of men. For the good has more than one aspect. The beautiful or noble when realized in action becomes the just. And to the question, What is just? are closely allied those other questions of Socrates—What is a state? What is it to be a statesman?

In the *Gorgias* Plato asserts the absolute supremacy of justice through the dramatic portraiture of Socrates in his opposition to the world; in the *Republic* he strives at greater length to define the nature of justice through the imaginary creation of an ideal community.

Gorgias. In the former dialogue the Platonic Socrates appears in direct antagonism with the Athenian world. The shadow of his fate is hanging over him. Chærephon (who is still alive) understands him, but to the other interlocutors, Gorgias, Polus, Callicles, he appears perversely paradoxical. Yet he effectively dominates them all. And to the reader of the dialogue this image of "Socrates contra mundum" is hardly less impressive than that former image of Socrates confronting death.

1. Gorgias asserts that rhetoric is an art concerned with justice, and that persuasion is the secret of power.

a. Socrates, after suggesting some ironical doubts, declares his opinion that rhetoric is no art, but a knack of pleasing, or in other words "the counterfeit of a subsection of statesmanship." This oracular definition rouses the interest of Gorgias, and Socrates proceeds with the following "generalization and division":—

Flattery influences men through pleasure without knowledge. And the rhetor is a kind of confectioner, who can with difficulty be distinguished from the sophist.

b. Rhetoric, then, is not an art. And persuasion is not the secret of power. Here Socrates maintains against Polus the three paradoxes:—

The tyrant does what he chooses but not what he wishes;

It is less evil to suffer wrong than to do wrong;

It is better for the wrongdoer to be punished than to escape punishment.

The only use of rhetoric, therefore, is for self-accusation, and (if it is ever permissible to do harm) to prevent the punishment of one's enemy.

2. Callicles here loses patience and breaks in. He propounds his theory, which is based on the opposition of nature and custom.

"There is no natural right but the right of the stronger. And natural nobility is to have strong passions and power to gratify them. The lawful

is a word that cowards use,
Devised at first to keep the strong in awe."

Socrates entangles him in an argument in which it is proved that pleasure is different from good, and that there are good and bad pleasures.

Now the question is whether the life of philosophy, or the life which Callicles defends, is conducive to good. And it has been shown that rhetoric is one of a class of pursuits which minister to pleasure without discriminating what is good.

Callicles again becomes impatient. Did not Themistocles, Cimon, Pericles labour for their country's good? Socrates then renews his demonstration, proving that if the just man is wronged the evil lies with the wrongdoer, not with him, and that it is worst for the wrongdoer if he escape. And for avoidance of this greatest evil not rhetoric avails anything, nor any of the arts which save life (seeing that life may be used well or ill), nor even such an art of politics as Themistocles, Cimon, or Pericles knew, but another science of politics which Socrates alone of the Athenians practises. The pursuit of it may well endanger him; but his strength lies in having done no wrong. For in the world to come he can present his soul faultless before her judge. Not the show of justice but the reality will avail him there.

This truth is enforced by an impressive myth. And Callicles is invited to leave the life which relies on rhetoric and to follow Socrates in practising the life of philosophic virtue.

The value of justice has been shown. But what is justice? Is the life upheld by Socrates sufficiently definite for practical guidance? The views of Callicles have been overborne; but have they been thoroughly examined? Socrates claims to be the only politician. But how can that deserve the name of policy which results in doing nothing? These and cognate questions may well have haunted Plato when he planned the greatest of his works.

Republic.

For that which lay deepest in him was not mere speculative interest or poetic fervour, but the practical enthusiasm of a reformer. The example of Socrates had fired him with an ideal of wisdom, courage, temperance, and righteousness, which under various guises, both abstract and concrete, has appeared and reappeared in the preceding dialogues. But the more vividly he conceived of this ideal life, the more keenly he felt its isolation in the present world—that of the restored Athenian democracy. For to a Greek mind above all others life was nothing without the social environment, and justice, of all virtues, could least be realized apart from a community. Hence it became necessary to imagine a form of society in which the ideal man might find himself at home, a state to which the philosopher might stand in harmonious relationship, no longer as an alien sojourner, but as a native citizen, not standing aloof in lonely contemplation, but acting with the full consent of other men and ruling in the right of wisdom. Plato did not regard his own republic as a barren dream. He believed that sooner or later in the course of time a state essentially resembling his ideal commonwealth would come into being. Still more firmly was he convinced that until then mankind would not attain their highest possible development. To ignore this real aspect of his most serious work is to lose much of the author's meaning. Yet it is hardly less erroneous to interpret a great imaginative creation *au pied de la lettre*, as if exam-

ining a piece of actual legislation. Even in his *Laws*, a far more prosaic writing, Plato himself repeatedly protests against such criticism. In his most aspiring flights he is well aware of the difference between the imaginary and actual embodiment of an ideal,¹ although as a literary artist he gives to his creations, whether in anticipation or retrospect, an air of sober reality and matter-of-fact. He is more in earnest about principles than about details, and if questioned would probably be found more confident with regard to moral than to political truth. He may have been wholly unconscious of the inconsistencies of his scheme, but it would not have greatly disconcerted him to have discovered them, or to have been told that this or that arrangement would not "work." He would have trusted the correction of his own rough draft to the philosopher-kings of the future.

The *Republic* falls naturally into five portions. (1) Bk. i. is preliminary, raising the main question about justice. (2) Bks. ii., iii., iv. contain the outlines of the perfect state, including the education of the "guardians," and leading up to the definition of justice (a) in the state, and (b) in the individual. (3) Bks. v., vi., vii. (which to some critics present the appearance of an afterthought or excrescence on the original design) contain the cardinal provisions (1) of communism (for the guardians only), (2) that philosophers shall be kings, (3) of higher education for the rulers (viz., the philosopher-kings). This third provision occupies bks. vi. and vii. (which have again, as some think, the appearance of an outgrowth from bk. v.). (4) Bks. viii. and ix., resuming the general subject from bk. iv., present the "obverse side," by showing the declension of the state and individual through four stages, until in the life of tyranny is found the image of ideal injustice, as that of justice was found in the life of the perfect state. (5) Bk. x. forms a concluding chapter, in which several of the foregoing enactments are reviewed, and the work ends, like the *Gorgias*, with a vision of judgment.

Thus the main outlines of the scheme are contained in bks. ii., iii., iv., viii., ix. And yet bks. v., vi., vii. form the central portion, a sort of inner kernel, and are of the highest significance.

In speculating about the composition of the *Republic* (as is the fashion of some interpreters), it is important to bear in mind the general character of Plato's writings.

"The conception of unity," says Professor Jowett,² "really applies in very different degrees to different kinds of art,—to a statue, for example, far more than to any kind of literary composition, and to some species of literature far more than to others. Nor does the dialogue appear to be a style of composition in which the requirement of unity is most stringent; nor should the idea of unity derived from one sort of art be hastily transferred to another. . . . Plato subjects himself to no rule of this sort. Like every great artist he gives unity of form to the different and apparently distracting topics which he brings together. He works freely, and is not to be supposed to have arranged every part of the dialogue before he begins to write. He fastens or weaves together the frame of his discourse loosely and imperfectly, and which is the warp and which the woof cannot always be determined."

It should be added, that as Dialectic was still a "world not realized," and he was continually conscious of using imperfect methods, he was not solicitous to bind himself to any one method, or to watch carefully over the logical coherence of his work. "Sailing with the wind of his argument," he often tacks and veers, changing his method with his subject-matter, much as a poet might adopt a change of rhythm. Absorbed as he is in each new phase of his subject, all that precedes is cancelled for the time. And much of what is to come is deliberately kept out of view, because ideas of high importance are reserved for the place where their introduction will have most effect. Another cause of apparent inconsequence in Plato is what he himself would call the use of hypothesis. He works less deductively and more from masses of generalized experience than Platonists have been ready to admit. And in the *Republic* he is as much engaged with the criticism of an actual as with the projection of an ideal condition of society.³ If we knew more of the working of

Attic institutions as he observed them, we should often understand him better.

These general considerations should be weighed against the inequalities which have led some critics to suppose that the "first sketch of the state" in bks. ii.-iv. is much earlier than the more exalted views of bks. v.-vii. If in these later books new conditions for choosing the future rulers are allowed to emerge, if in discussing the higher intellectual virtues the simple psychology of bk. iv. is lost sight of (it reappears in the *Timæus*), if the "knowledge of the expedient" at first required falls far short of the conception of knowledge afterwards attained, all this is quite in keeping with Plato's manner elsewhere, and may be sufficiently accounted for by artistic and dialectical reserve. It can hardly be an altogether fortuitous circumstance that the culminating crisis, the third and highest wave of difficulty,—the declaration that philosophers must be kings and kings philosophers,—comes in precisely at the central point of the whole long work.

The great principle of the political supremacy of mind, though thus held back through half the dialogue, really dominates the whole. It may be read between the lines all through, even in the institution of gymnastic and the appraisal of the cardinal virtues. It is a genuine development of Socratic thought. And it is this more than any other single feature which gives the *Republic* a prophetic significance as "an attempt towards anticipating the work of future generations."⁴

Other aspects of the great dialogue, the Dorian framework, so inevitable in the reaction from Ionian life, the traces of Pythagorean influence, the estimate of oligarchy and democracy, the characters of the interlocutors in their bearing on the exposition, have been fully treated by recent writers, and for brevity's sake are here passed over.

There are other points, however, which must not be omitted, because they are more intimately related to the general development of Plato's thoughts.

1. The question debated by Proclus has been raised before and since, whether the proper subject of the *Republic* is justice or the state. The doubt would be more suggestive if put in a somewhat different form: Is Plato more interested in the state or the individual? That he is in earnest about both, and that in his view of them they are inseparable, is an obvious answer. And it is almost a truism to say that political relations were prior to ethical in the mind of a Greek. Yet if in some passages the political analogy reacts on moral notions (as in the definition of temperance), in others the state is spoken of in language borrowed from individual life. And it remains questionable whether the ethics or the politics of the *Republic* are less complete. On the whole Plato himself seems to be conscious that the ideal derived from the life-work of Socrates could be more readily stamped on individual lives than on communities of men (see especially *Rep.*, vii. 528 A, ix. 592).

2. The analogy of the individual is often used to enforce the requirement of political unity and simplicity (see especially v. 462 C). This is also to be referred, however, to Plato's general tendency to strain after abstractions. He had not yet reached a point of view from which he could look steadily on particulars in the light of universal principles. He recurs often to experience, but is soon carried off again into the abstract region which to him seemed higher and purer.⁵ "It has been said that Plato flies as well as walks, but this hardly expresses the whole truth, for he flies and walks at the same time, and is in the air and on firm ground in successive instants" (Jowett).

⁴ Grote.

⁵ See, for example, the admission of luxury and the after-purification through "music," bks. ii., iii.

Plato's scheme of communism had been suggested to him partly by Dorian institutions and partly by the Pythagorean rule. But it was further commended by the general consideration that the state is a higher and more abstract unity than the family. The lower obligation must give way to the higher; the universal must overrule the particular bond.

3. Similarly it may be argued that, while the subordination of music to state discipline, and the importance attached to rhythm and harmony in education, had likewise a connexion with Sparta and the Pythagoreans severally, Plato's deliberate attitude towards poetry and art could hardly be other than it is. Philosophy, while still engaged in generalization, could not assign to the imagination its proper function. "Æsthetik" could not enter into her purview. For a moment, in the *Symposium*, the ancient quarrel of poetry and philosophy had seemed to be melted in a dominant tone, but this was only a fond anticipation. Plato, if man ever did so, had felt the siren charm, but he is now embarked on a more severe endeavour, and, until the supreme unity of truth and good is grasped, vagrant fancy must be subdued and silent.

4. In the early education of the guardians a place is found for the unconscious virtue acquired through habit which the *Protagoras* and *Meno* stumbled over and the *Phædo* treated with disdain. In the ideal state, however, this lower excellence is no longer a wild plant, springing of itself through some uncovenanted grace of inspiration, but cultivated through an education which has been purified by philosophy so as to be in harmony with reason. But if Plato were cross-questioned as to the intrinsic value of habits so induced as a preservative for his pupils against temptation, he would have replied, "I do not pretend to have removed all difficulties from their path. Enough of evil still surrounds them to test their moral strength. I have but cleared the well-springs of the noxious weeds that have been fatal to so many, in order that they may have little to unlearn, and be exposed only to such dangers as are inevitable."

5. It is a singular fact, and worth the attention of those who look for system in Plato, that the definition of justice here so laboriously wrought out, viz., the right division of labour between the three classes in the state and between the three corresponding faculties in the individual soul, is nowhere else repeated or applied, although the tripartite division of the soul recurs in the *Timæus*, and the notion of justice is of great importance to the arguments of the *Politicus* and the *Laws*.

6. Before leaving the *Republic*, it is important to mark the stage which has now been reached by Plato's doctrine of ideas. The statements of the *Republic* on this subject are by no means everywhere consistent.

a. Towards the end of bk. v. philosophers are defined as lovers of the whole, who recognize the unity of justice, goodness, beauty, each in itself, as distinguished from the many just or good or beautiful things. The former are said to be objects of knowledge, the latter of opinion, which is intermediate between knowledge and ignorance. Knowledge is of being, ignorance of the non-existent, opinion of that which is and is not.

b. In bk. vi. there is a more elaborate statement, implying a more advanced point of view. The "contemplation of all time and all existence" is a riper conception than "the love of each thing as a whole." Ignorance and nonentity have now disappeared, and the scale is graduated from the most evanescent impression of sense to the highest reach of absolute knowledge. And in the highest region there is again a gradation, rising to the form of good, and descending from it to the true forms of all things. In the application of this scheme to the theory

of education in bk. vii. there are still further refinements. The psychological analysis becomes more subtle, and more stress is laid on the connexion of ideas.

c. The doctrine reverts to a cruder aspect in bk. x., where we are told of an ideal bed, which is one only and the pattern of all the many actual beds.

d. A yet different phase of idealism presents itself in bk. ix. (*sub fin.*), in the mention of a "pattern" of the perfect state laid up in heaven which the philosopher is to make his rule of life.

What is said above concerning Plato's mode of composition has some bearing on these inconsistencies of expression. And that bks. vi., vii., as being the most important, were finished last is a not untenable hypothesis. But that Plato, in preparing the way for what he had in contemplation, should content himself with provisional expressions which he had himself outgrown, or that in a casual illustration (as in bk. x.) he should go back to a crude or even childish form of his own theory, is equally conceivable and in accordance with his manner elsewhere. Socrates in the *Parmenides* confessedly wavers on this very point. And there are "ideas" of the four elements in the *Timæus*.

VI. *Euthydemus*, *Parmenides*, *Theætetus*, *Sophist*, *Statesman*, *Philebus* (the dialectical dialogues).—Even in the most advanced metaphysics of the *Republic* there is a hyperbolic, transcendental tendency, from which Plato ultimately to some extent worked himself free. But it was not in conversation with "dear Glaucon," or "between the lines" of an ethico-political writing, that this partial emancipation could be effectually attained. We have now to consider a series of dialogues, probably intended for a narrower circle of readers, in which Plato grapples directly with the central difficulties of his own theory of knowing and being. It is not necessary to assume that all of these are later than the *Republic*. The position of the *Euthydemus* and *Parmenides* in the order of composition is very uncertain. The *Theætetus* has points of affinity with the *Republic*. The *Sophist*, *Politicus*, and *Philebus* are in a later style. But, on account of their cognate subject-matter, these six dialogues may be conveniently classed together in a group by themselves. And the right place for such a group is intermediate between the *Republic* and the *Laws*.

The dialectical dialogues.

The unity of the object of definition, the identity of virtue and knowledge, the existence of an absolute good, which would be universally followed if universally known, and of a standard of truth which is implied in the confession of ignorance, were postulates underlying the Socratic process, which in so far made no claim to be a "philosophy without assumptions." These postulates, when once apprehended, drew Plato on to speculate concerning the nature, the object, and the method of knowledge. Now, so far as we have hitherto followed him, his speculation has either been associated with ethical inquiry, or has been projected in a poetical and semi-mythical form. In the *Phædrus*, however, the vision of ideas was expressly conjoined with an outline of psychology and a foreshadowing of scientific method. And, while the opposition of ideas to phenomena and of knowledge to opinion has been repeatedly assumed, it has also been implied that there is a way between them, and that the truth can only be approached by man through interrogation of experience. For it is nowhere supposed that the human inquirer is from the first in a position to deduce facts from ideas. Much rather, the light of the ideas is one which fitfully breaks in upon experience as men struggle towards the universal.

But it is not less true that the metaphysical aspirations from which Socrates had seemed to recall men's thoughts had been reawakened in consequence of the impulse which

Socrates himself had given. From asking, Is virtue one? Can virtue be taught? Plato passes on to ask, What is unity? What are knowledge and being? From criticizing imperfect modes of teaching virtue, he has begun to speculate about the right and wrong uses of the intellect, and from dramatic portraits of the individual Protagoras or Gorgias goes on to the ideal delineation of the sophist. He has entered upon the "longer way," and is no longer contented with mere "hypotheses." With this demand for scientific precision his conception of the ideas themselves is modified, and he strives anew to conceive of them in relation to one another, to the mind, and to the world. As the balance of ethical truth was restored by admitting an unconscious (or inspired) conformity to reason, so now a fresh attempt is made on the intellectual side to bridge the gulf between sense and knowledge.

This endeavour involves, not only an expansion of the method of Socrates, but an examination of the earlier philosophies from which Socrates had turned away. Their influence on Plato has been traceable in the preceding dialogues, though, except in the case of Pythagoreanism (*Phæd.*, *Rep.*), it has been mostly indirect and casual. But in these dialectical dialogues he manifests his serious conviction that the contemporary fallacies which formed the chief hindrance to inquiry were deeply rooted in forms of thought created by earlier thinkers, above all by Heraclitus and Parmenides. To the exclusiveness of their first principles as held by their followers Plato attributed the barrenness and impracticable unreality of many discussions, which put shadow-fighting and controversy in the place of real investigation, and led men to think that truth was unattainable. He therefore enters into conversation, as it were, with the great minds of former times, and in the spirit of Socrates compels each of them to yield up his secret, and to acknowledge a supplemental truth. To this effort he may very probably have been stimulated by the dialectical activity of his Socratic friends at Megara, whose logical tastes had drawn them towards Eleaticism. But, unlike them, while strengthening his metaphysical theory, he was also led to give to his political speculations a more practical turn.

Euthydemus.

The *Euthydemus* is a treatise "De Sophisticis Elenchis" in the form of a farce, and may serve to introduce the five other dialogues, as the encounter with Thrasymachus introduces the serious part of the *Republic*. Under the veil of mockery there is more of concentrated thought, and also more of bitterness, in this dialogue than in the *Protagoras* or the *Gorgias*.

A sample of educational dialectic—in which Socrates draws out of young Clinias the admissions (1) that a philosophy is needed, (2) that the highest philosophy is a science of king-craft, which remains for the present undefined,—is contrasted with a series of ridiculous sophisms, propounded by Dionysodorus and his brother Euthydemus, in which absolute and relative notions, whether affirmative or negative, object and subject, universal and particular, substance and attribute, action and modality, are capriciously confused. Crito, to whom Socrates narrates the scene, is moved to contempt. But Socrates warns him not on this account to despair of philosophy. In conclusion, Isocrates, or some one else, who prematurely mixes up philosophy with practical politics, is cautioned against spoiling two good things.

Such puzzles as—How can I learn either what I know or what I do not know?¹ How can things become what they are not? How is falsehood or denial possible?—although treated jocularly here, will be found returning afterwards to "trouble the mind's eye."

Plato appears in the same act to have become aware of Parmenides' affinity with Parmenides, and to have been led to reconsider the foundations of his own doctrine. The one being of Parmenides was a more abstract notion than justice, beauty, or the good. And the Zenonian method had more pretension to exactness than the Socratic. But it remained barren, because contented to repeat its own first essays in the destructive analysis of experience, without rising to the examination of its own first principles. For this higher criticism, of which he himself also stood in need, Plato looks up from the disciples to the master, Parmenides. The appeal to him is put into the mouth of Socrates, as a very young man, who has framed for himself a theory of ideas, and would gladly see the Zenonian process applied to the notions of sameness, difference, likeness, unlikeness, unity, and being.

Parmenides, whom Plato treats with tender reverence not unmixed with irony, proposes to the youth a series of questions which reveal the crudity of the doctrine of *εἶδη*. (1) Are there ideas of trivial things?² (2) How do things "partake" of them? (3) Must not idealism proceed *in infinitum*? (4) If ideas are thoughts, do they and their participants think? (5) If they are patterns, and things resemble them, must there not be a pattern of the resemblance, and so on *in infinitum*? (6) If absolute, are they thinkable by man?

These difficulties are real, and yet to deny ideas is to destroy philosophy. (As the paradoxical doubts in the *Protagoras* do not shake the faith of Socrates in the existence of good, so neither does Plato here intend for a moment to derogate from the belief in the existence of the One and the True.)

Parmenides advises Socrates to arm himself for the further pursuit of truth (1) by the higher application and (2) by the extension or completion of the Zenonian method. (1) The method is to be applied to abstractions. (2) It is not enough to show the inferences which may be drawn from the admission of an hypothesis, but account must also be taken of the inferences which follow from its rejection.

Parmenides exemplifies his suggestion by examining his own first principle in conversation with a youth who, while a contemporary of Socrates, is a namesake of Plato's pupil Aristotle.³ Not content with the affirmative and negative hypotheses, he pursues either along two lines, according as either term of the proposition is emphasized, and this not only as regards the hypothesis of unity, but also as applied to the alternative hypothesis of plurality. The result, as in the *Protagoras*, is purely destructive, and the dialogue ends abruptly without a word of reply from Socrates.

The second part of the *Parmenides* may be regarded as an experiment in which Plato "assays to go" in Eleatic armour. Yet the strange web is "shot" with colours of original thought. The mode of conceiving time and becoming, and the vision of nothingness towards the end, may be noted as especially Platonic. These passages may be regarded in the same light as the wise words of Protagoras or the sober truths which occur amidst the wild fancies of the *Cratylus*. They should not mislead the interpreter into a search for recondite meanings.

The Zenonian method has been carried out to the utmost in application to the highest subject, and has led the mind into a maze of contradiction. It remains to call in question the method itself, and the notion of absolute identity and difference on which it hinges, and so to lay anew the foundation-stone of thought.

Before this can be attempted, however, another set of difficulties have to be met, and another set of philosophers examined. For the current scepticism had undermined the conception of knowledge as well as that of being, and the fame of Heraclitus was hardly second to that of Parmenides. Protagoras appeared in a former dialogue as

² Comp. *Rep.*, x, 597.

³ Comp. the younger Socrates of the *Politics*. It would be precarious to draw any inference from this minute fact.

¹ Comp. *Meno*.

Theaet. the champion of ordinary morality; he is now made the exponent of ordinary thinking. His saying "Man the measure" is shown to rest on the unstable basis of the Heraclitean flux. By an elaborate criticism of both theories knowledge is at last separated from the relativity of sense; but the subsequent attempt to distinguish on abstract grounds between true and false opinion, and to define knowledge as true opinion with a reason (comp. *Meno*), proves ineffectual. Plato still shows traces of Megarian influence. But the disjunctive method of the *Parmenides* is not resumed. The indirect proofs are so arranged as to exhibit the skill of Socrates in "bringing to the birth" the germs of thought in a richly-endowed and "pregnant" young mind. Theaetetus is the embodiment of the philosophic nature described in *Rep.*, bk. vi., and has already been trained by Theodorus of Cyrene in geometry and the other preparatory sciences of *Rep.*, bk. vii. It is in conversation with Theodorus that Socrates impressively contrasts the lives of the lawyer and the philosopher. The *Theaetetus* marks a great advance in clearness of metaphysical and psychological expression. See for example the passage (184-186) in which the independent function of the mind is asserted, and ideas are shown to be the truth of experience. There is also a distinct approach towards a critical and historical method in philosophy, while the perfection of style continues unimpaired, and the person of Socrates is as vividly represented as in any dialogue.

Notwithstanding the persistence of an indirect and negative method, the spirit of this dialogue also is the reverse of sceptical. "Socrates must assume the reality of knowledge or deny himself" (197 A). Perhaps in no metaphysical writing is the balance more firmly held between experience, imagination, and reflexion. Plato would seem to have made a compact with himself to abstain rigidly from snatching at the golden fruit that had so often eluded his grasp, and to content himself with laboriously "cutting steps" towards the summit that was still unscathed.

Sophist. With Plato, as with other inventive writers, a time seems to have arrived when he desired to connect successive works in a series. Thus in planning the *Sophistes* he linked it to the *Theaetetus* (which had been written without any such intention), and projected a whole tetralogy of dialectical dialogues, *Theaetetus*, *Sophistes*, *Politicus*, *Philosophus*, of which the last piece seems never to have been written.

After an interval, of which our only measure is a change of style, the philosopher returns to the great central question of knowledge and being. The obstacle in his path, on which he has often played with light satire, dramatic portraiture, and indirect allusion, is now to be made the object of a seriously planned attack. He has made his approaches, and the enemy's fortress is to be forthwith sapped and overthrown. This hostile position is not merely the "Sophistik" which, as some tell us, is an invention of the Germans, and as Plato himself declares is only the reflexion or embodiment of the average mind,¹ but the fallacy of fallacies, the prime falsehood (*πρῶτον ψεῦδος*) of all contemporary thought. This is nothing else than the crude absoluteness of affirmation and negation which was ridiculed in the *Euthydemus*, and has been elsewhere mentioned as the first principle of the art of controversy.² For dramatic purposes this general error is personified. And the word "sophist," which had somehow become the *bête noire* of the Platonic school, thus for the first time fixedly acquires the significance which has since clung to the name.—That Plato himself would not adhere pedantically to the connotation here implied is shown by

the admission, at the opening of the dialogue, that amongst other disguises under which the philosopher walks the earth, the sophist is one.—In this dialogue, as in the *Parmenides*, a new method is introduced, and again by an Eleatic teacher. This method is repeated with improvements in the *Politicus*, and once more referred to in the *Philebus*. It bears a strong resemblance to the "synagoge" and "diaeresis" of the *Phædrus*, but is applied by the "friend from Elea" with a degree of pedantry which Socrates nowhere betrays. And the two methods, although kindred, have probably come through different channels,—the classifications of the *Phædrus* being Plato's own generalization of the Socratic process, while the dichotomies of the *Sophistes* and *Politicus* are a caricature of Socrates cast in the Megarian mould. Plato seems to have regarded this method as an implement which might be used with advantage only when the cardinal principles on which it turned had been fully criticized.

1. After various attempts to "catch the sophist," he is defined as the maker of an unreal likeness of truth. Here the difficulty begins—for the definition implies the existence of the unreal, i.e., of not-being. In our extremity it is necessary to "lay hands on our father Parmenides."

2. The contradictions attendant on the notion of "being," whether as held by Parmenides or his opponents or by the "less exact" thinkers who came after them, are then examined, and in an extremely subtle and suggestive passage (246-249) an attempt is made to mediate between idealism and materialism. The result is that while consummate being is exempt from change it cannot be devoid of life and motion. "Like children, 'Give us both,' say we."

3. This leads up to the main question:—(a) are different notions incommunicable, or (b) are all ideas indiscriminately communicable, or (c) is there communion of some kinds and not of others? The last view is alone tenable, and is confirmed by experience. And of the true combination and separation of kinds the philosopher is judge.

4. Then it is asked (in order to "bind the sophist") whether being is predicable of not-being.

Five chief kinds (or categories) are now examined, viz., being, rest, motion, sameness, difference. Rest and motion are mutually incommunicable, but difference is no less universal than being itself. For everything is "other" than the rest, i.e., is not. Thus positive and negative not only coexist but are coextensive.

5. And, in spite of Parmenides, we have discovered the existence, and also the nature, of not-being. It follows that the mere pursuit of contradictions is childish and useless and wholly incompatible with a philosophic spirit.

Negation, falsity, contradiction, are three notions which Plato from his height of abstraction does not hold apart. His position is the converse of the Spinozistic saying, "Omnis determinatio est negatio." According to him, every negative implies an affirmative. And his main point is that true negation is correlative to true affirmation, much as he has said in the *Phædrus* that the dialectician separates kinds according to the "lines and veins of nature." The *Sophistes* is a standing protest against the error of marring the finely-graduated lineaments of truth, and so destroying the vitality of thought.

The idealists whom the Eleatic stranger treats so gently have been identified with the Megarians. But may not Plato be reflecting on a Megarian influence operating within the Academy?

Here, as partly already in the *Parmenides* and *Theaetetus*, the ideas assume the nature of categories, and being is the sum of positive attributes, while negation, as the shadow of affirmation, is likewise finally comprehended in the totality of being.

The remark made incidentally, but with intense emphasis, that the universe lives and moves "according to God," is an indication of the religious tone which reappears increasingly in the *Politicus*, *Philebus*, *Timæus*, and *Laws*.

In passing on to consider the statesman, true and false, Politicus the Eleatic stranger does not forget the lesson which has just been learned. While continuing his method of dichotomies (Statesman.)

¹ *Rep.*, vi. 493.

² ἀντιλογική.

tomies, he is careful to look on both sides of each alternative, and he no longer insists on dividing between this and not-this when another mode of classification is more natural. A rule not hitherto applied is now brought forward, the rule of proportion or right measure (*τὸ μέτρον*), as distinguished from arbitrary limitations. Nor is formal logical treatment any longer felt to be adequate to the subject in hand, but an elaborate myth is introduced. On the ethico-political side also a change has come over Plato. As he has stripped his ideas of transcendental imagery, so in reconsidering his philosopher-king he turns away from the smiling optimism of the *Republic* and looks for a scientific statesmanship that shall lay a strong grasp upon the actual world. He also feels more bitterly towards the demagogues and other rulers of Hellas. The author of the *Politicus* must have had some great quarrel with mankind. But so far as they will receive it he is still intent on doing them good.

1. The king is first defined as a herdsman of men, who as "slow bipeds" are distinguished from the pig and the ape. But the king is not all in all to his charges, as the herdsman is. The above definition confuses human with divine rule.

2. Now the universe is like a top, which God first winds in one direction and then leaves to spin the other way. In the former or divine cycle all was spontaneous, and mankind, who had all things in common, were under the immediate care of gods. They were happy, if they used their leisure in interrogating nature. But in this reign of Zeus it is far otherwise. Men have to order their own ways and try to imitate in some far-off manner the all-but forgotten divine rule.

3. Therefore in our present definition the term "superintendent" must be substituted for "herdsman."

What special kind of superintendence is true statesmanship?

4. By way of an example, the art of weaving is defined. The example shows that kingcraft has first to be separated from other kindred arts, both causal and co-operative. Nine categories are adduced which exhaust social functions. Eight are eliminated, and the ninth, the class of ministers, remains. Of these (a) slaves, (b) hirelings, (c) traders, (d) officials, (e) priests are again parted off, although the last are only with difficulty separated from the king, when (f) a strange medley of monstrous creatures come into view. Some are fierce like lions, some crafty like the fox, and some have mixed natures like centaurs and satyrs. These are the actual rulers of mankind, more sophisticated and juggling than the sophist himself. And they too must be separated from the true king.

5. The familiar tripartite distinction of monarchy, oligarchy, democracy, is doubled by introducing into each the distinction involved in the presence or absence of wealth, and in the observance or non-observance of law. But no one of the six carries in itself a scientific principle.

The true government is the rule, not of many, but of one or of a few. "And they may govern, whether poor or rich, by freewill or compulsion, and either with or without law, so long as they govern scientifically."

6. The respondent, a youthful namesake of Socrates, is shocked at the remark that the true ruler may govern without law.

This leads to a discussion of the nature of law, which is compared to the prescription left by a physician. If present, he might dispense with his own rule. So the presence of a competent ruler is better than the sovereignty of law, which makes no allowance for nature or circumstance, but tyrannically forces its own way. Imagine medicine, navigation, &c., similarly conducted by time-honoured prescription, with penalties for innovation;—what would become of civilization? Yet if law is disregarded by rulers who are unscientific and warped by self-interest, this leads to far worse evils. For the laws are based on some experience and wisdom. Hence, in the continued absence of the true ruler, the best course, though only second best, is the strict observance of law. And he who so rules in humble imitation of the scientific governor may be truly called a king, although if the divine lawgiver were to appear his living will would supersede the law.

7. As it is, though cities survive many evils, yet many are shipwrecked because of the ignorance of those at the helm. The order of badness in the actual states is—

1. Constitutional monarchy.
2. Constitutional oligarchy.
3. Law-abiding democracy.
4. Law-breaking democracy.
5. Law-defying oligarchy.
6. Tyranny.

8. It remains to separate from the true ruler those who co-operate with him as subordinates, the general, the judge, the orator. His

own peculiar function is an art of weaving strength (the warp) with gentleness (the woof), when education has prepared them,—and this (1) by administration, (2) by marriage.

The four preceding dialogues have shown (1) the gradual transformation of the Platonic ideas (while still objective) into forms of thought, (2) the tendency to group them into series of categories, (3) a corresponding advance in psychological classification, (4) an increasing importance given to method, (5) the inclination to inquire into processes (*γενέσεις*) as well as into the nature of being.

Meanwhile Plato's approach to the Eleatics, though in the way of criticism, has brought into prominence the notions of unity, being, sameness, difference, and has left somewhat in abeyance the idea of good. To this "highest of Philebus, all studies" Plato now returns, equipped with his improved instruments, and ready to forge new ones in the same laboratory, or in some other, should occasion serve. His converse with Parmenides ended in his assertion of an element of difference pervading all things, in other words, of an indeterminate element underlying all determinations. This brings him again into relation with the Pythagoreans, who had similarly asserted the combination of finite and infinite in the universe.

Taking advantage of their help, he gains a more advanced (but still ideal) conception of the concrete harmony of things, and approaches the definition of that which in the *Republic* he but shadowed forth.

With this most serious inquiry there is combined (as in the *Sophistes* and *Politicus*) an ironical and controversial use of dialectic, by which the juggler and false pretender (who is in this case the goddess of pleasure), after claiming the highest place, is thrust down to the lowest.

It must be admitted that the style of the *Philebus* is far from brilliant, or even clear. In the effort of connecting abstractions Plato's movement is more laboured than in his first glad realization of them.

Instead of attempting here to follow the windings of the dialogue, it must suffice to state the main result. Neither pleasure nor knowledge is the highest good, and the good eludes definition; but the shrine, or habitation, of the good is a complex life of which the elements are, in order of merit—(1) measure, the cause of all right mixture; (2) (a) beauty, the effect, and (b) reality, the inseparable condition; (3) intellect; (4) science, art, and right opinion; (5) pure pleasure unaccompanied with pain. "Not all the animal kingdom shall induce us to put pleasure first."

The *Philebus* introduces us to the interior of the Academy in the lifetime of the master. More than any other of the dialogues it recalls Aristotle's description of Plato's teaching. But, while his followers seem early to have fallen under the dominance of the latest phase of his doctrine, Plato himself, even in the *Philebus*, is still detached from any servitude to the creations of his own mind. He manipulates them as the medium for expressing his fresh thoughts, but they are not yet crystallized into a system.

"I will remind you," Socrates, "of what has been omitted," says Protarchus at the conclusion of this dialogue. The last (presumably) of Plato's metaphysical writings thus fitly ends with a confession of incompleteness. But if, as M. Renan says, "the most fatal error is to believe that one serves one's country by calumniating those who founded it," neither is it for the interest of science to ignore these imperfect anticipations. By methods elaborated in the course of centuries, and far more sure than any which Plato had at his command, mankind have gained an extent of knowledge which he dreamt not of.¹ But the Greek metaphysician is none the

¹ See, however, *Polit.*, 272 C, D.

The imaginative dialogues.

less a pioneer of knowledge,¹ while the special sciences of ethics and psychology had been carried from infancy to adolescence in a single lifetime.

VII. *Timæus*, *Critias*, [*Hermocrates*].—As the *Sophistes* and *Politicus* were written in continuation of the *Theætetus*, so, at some uncertain time, Plato conceived the design of writing a great trilogy, for which the ideal state depicted in the *Republic* should be the point of departure. The grand outline there sketched by Socrates was now to be filled up by Critias and Hermocrates. The form set up by reasoning should be made alive, the "airy burghers" should be seen "making history." As a prelude to this magnificent celebration, Timæus, the Pythagorean philosopher, who is present at the Panathenæa, is invited to discourse of the origin of all things, and to bring down the glorious theme to the creation of man. What should have followed this, but is only commenced in the fragment of the *Critias*, would have been the story, not of a fall, but of the triumph of reason in humanity.

In the *Philebus* (59 A, comp. 62 D) Plato speaks with a touch of contempt of the life-long investigation of nature, as being concerned only with this visible universe, and immersed in the study of phenomena, whether past, present, or to come, which admit of no stability and therefore of no certainty. "These things have no absolute first principle, and can never be the objects of reason and true science."

Yet even this lower knowledge is there admitted as an element of that life which is the habitation of the good. And there are not wanting signs in his later dialogues that Plato's imagination had again been strongly drawn towards those physical studies which, as the *Phædo* shows, had fascinated him in youth. That nature and the world proceed "according to God and not according to chance" is the belief of the Eleatic stranger, to which he perceives that Theætetus will be irresistibly drawn as he grows older. In the midst of dialectical abstractions, the processes of actual production (*γενέσεις*) have been increasingly borne in mind. And the myth in the *Politicus* turns on cosmological conceptions which, although differing from those in the *Timæus*, and more accordant with Plato's bitterest mood, yet throw a new light on the deeper current of his thoughts. In the same passage (272 C) there occurs the first clear anticipation of an *interrogatio naturæ*.

The impulse in this new direction, if not originated, was manifestly reinforced, through closer intercourse with the Pythagorean school. And the choice of Timæus the Pythagorean as chief speaker is an acknowledgment of this obvious tendency. If in the course of the dialogue there occur ideas apparently borrowed from the Atomists, whom Plato persistently ignored, this fact ought probably to be referred to some early reaction of Atomic on Pythagorean doctrine. It is important to observe, however, that not only the *Timæus*, but the unfinished whole of which it forms the introduction, is professedly an imaginative creation. For the legend of prehistoric Athens and of Atlantis, whereof Critias was to relate what belonged to internal policy and Hermocrates the conduct of the war, would have been no other than a prose poem, a "mythological lie," conceived in the spirit of the *Republic*, and in the form of a fictitious narrative. And, therefore, when Timæus professes to give only a probable account of shadowy truths, he must be taken at his word, and not criticized in too exacting a spirit. His descriptions have much the same relation to the natural philosophy of Plato's time that Milton's cosmology has to the serious investigations of Galileo or Copernicus,—except that all physical

speculation hitherto partook in some measure of this half-mythological character, and that Plato's mind, although working in an unfamiliar region, is still that of a speculative philosopher.

As Parmenides, after demonstrating the nonentity of Timæus, growth and decay, was yet impelled to give some account of this non-existent and unintelligible phenomenal world, so Plato, although warned off by Socrates, must needs attempt to give a probable and comprehensive description of the visible universe and its creation. In doing so he acknowledges an imperfect truth in theories which his dialectic had previously set aside. In examining the earlier philosophers he has already transgressed the limits prescribed by Socrates, and the effort to connect ideas has made him more and more conscious of the gap between the ideal and the actual. He cannot rest until he has done his utmost to fill up the chasm—calling in the help of imagination where reason fails him.

His dominant thought is still that of a deduction from the "reason of the best," as in the *Phædo*, or "the idea of good," as in the *Republic*. But both his abstract idealism and his absolute optimism were by this time considerably modified, and, although not confounding "causes with conditions," as he once accused Anaxagoras of doing, he yet assigns more scope to "second causes" than he would then have been willing to attribute to them. This partly comes of ripening experience and a deepening sense of the persistency of evil, and partly from the feeling—which seems to have grown upon him in later life—of the distance between God and man.

Timæus begins by assuming (1) that the universe being corporeal is caused and had a beginning, and (2) that its mysterious author made it after an everlasting pattern. Yet, being bodily and visible, it can only be made the subject, humanly speaking, of probable discourse.

Thus much being premised, he proceeds to unfold—(A) the work of mind in creation, (B) the effects of necessity, including the general and specific attributes of bodies, (C) the principles of physiology, and (D) an outline of pathology and medicine.

To give a full account of such a comprehensive treatise is beyond the scope of this article, and the *Timæus*, however great and interesting, has been well described as an out-building of the great fabric of original Platonism. A very few scattered observations are all that there is space for here.

(A) 1. In the mythology of the *Timæus* some of the conceptions which attained logical clearness in the *Sophist* and *Philebus* resume an ontological form. Thus, in compounding the soul-stuff of the universe, the father of all takes of the continuous and discrete and fuses them into an essence (the composite being of the *Philebus*). Again he takes of the same and other (comp. the *Sophist*), overcoming their inherent repugnance by his sovereign act.

2. The notion of an economy or reservation in Plato has been often exaggerated and misapplied. But it is difficult to acquit him of intentional obscurity in speaking of the creation of the Earth. It is clear, though Plato does not say so, that she is meant to have been created together with the Heaven and together with Time, and so before the other "gods within the heaven," i.e., the sun and moon and five planets, and it is a plausible supposition that she is the "artificer of day and night" by interposing her bulk to the sun's rays. If the word *εἰλωμένη* in p. 40 implies motion (as Aristotle thought²), it cannot be, as Grote supposed, a motion consentaneous with that of the outer sphere, but either some far slower motion, perhaps assumed in order to account for the shifting of the seasons, or an equal retrograde motion which is supposed to neutralize in her case the "motion of the same." She clings to the centre, as her natural abode. And the diurnal motion of the heavens is due not to any mechanical force but to the soul of the world extending from the centre to the poles and comprehending all.

3. Immortality is in the *Timæus* dependent on the will of the Eternal. And the sublime idea of eternity is here first formulated.

4. The phenomena of vision and hearing are included among the works of reason, because the final cause of these higher senses is to give men perception of number, through contemplation of the measures of time.

(B) 1. It has been commonly said that the four elements of the *Timæus* are geometrical figures, without content. This is not true. For what purpose does Plato introduce, "besides the archetype and

¹ See Jowett, *Introd. to the Timæus*.

² Aristotle, however, uses *εἰλωμένη*, a different word.

the created form, a third kind, dim and hard to conceive, a sort of limbec or matrix of creation," if not to fill up the triangles which are elements of elements, and to be the vehicle of the forms compounded of them? It has been supposed that this "nurse of generation" is identical with "space," and it cannot be said that they are clearly kept apart by Plato. But he had a distinct nomenclature for either, and, although gravity is explained away (so that his molecules, unlike Clerk Maxwell's, may be called imponderable), yet extension, or the property of filling space, is sufficiently implied.

2. The difference of size in the triangles and varying sharpness of their outlines are ingenious though inadequate expedients, adopted in order to account for qualitative difference and physical change.

3. In criticizing the illusory notion of up and down Plato broaches the conception of antipodes.

4. More distinctly than in the *Philebus*, bodily pleasure is explained by "a sudden and sensible return to nature" (comp. *Ar., Rhet.*, i. 11, § 1; *N. E.*, vii. 10).

5. Natural philosophers are warned against experimenting on the mixture of colours, which is a divine process and forbidden to man.

(C) 1. Plato tends more and more in his later writings to account for moral evil by physical conditions, thus arriving at the Socratic principle of the involuntariness of vice by a different road.

Hence in the *Timæus* not the body only is made by the inferior gods, but they also create the lower and mortal parts of the human soul:—the principle of anger which is planted in the breast, within hearing of reason, and that of appetite which is lodged below the diaphragm like an animal tied in a stall, with the stomach for a crib and the liver for a "soothsaying" looking-glass to soothe or terrify it when tempted to break loose.

2. The brain-pan was left bare of protecting flesh "because the sons of God who framed us deliberately chose for us a precarious life with capability of reason, in preference to a long secure existence with obstruction of thought."

3. The nails are a rudimentary provision for the lower animals, into which degenerate souls were afterwards to be transformed.

4. Vegetables have sensation but not motion.

5. By way of illustrating the very curious account here given of respiration, it is asserted that what is commonly thought to be the attraction of the magnet is really due to rotatory motion and displacement.

6. When the original particles wear out, and the bonds of soul and body in the marrow give way, the soul escapes delightedly and flies away. This is the painless death of natural decay.

(D) 1. The dependence of mental disease on bodily conditions is more fully recognized in the *Timæus* than elsewhere in Plato (contrast the *Charmides*, for example).

2. He has also changed his mind about the treatment of disease, and shows more respect for regimen and diet than in the *Republic*. Diseases are a kind of second nature, and should be treated accordingly.

3. It is also a remark in contrast with the *Republic*, that over-study leads to head complications, which physicians ascribe to chill and find intractable.

Lastly, it is one of the strange irregularities in the composition of the *Timæus* that the creation of woman and the relation of the sexes¹ to each other are subjects reserved to the end, because this is the place given to the lower animals, and woman (compare the *Phædrus*) is the first transmigration from the form of man. This order is probably not to be attributed to Plato's own thought, but to some peculiarity of Pythagorean or Orphic tradition.

VIII. *The Laws*.—The two series of dialogues, the dialectical and the imaginative,—*Sophistes*, *Politicus*, *Philosophus*,—*Timæus*, *Critias*, *Hermocrates*,—were left incomplete. For Plato had concentrated his declining powers, in the evening of his life,² upon a different task. He was resolved to leave behind him, if he could so far overcome the infirmities of age,³ a code of laws, conceived in a spirit of concession, and such as he still hoped that some Hellenic state might sanction. The motive for this great work may be gathered from the *Politicus*. The physician in departing is to give a written prescription, adapted as far as possible to the condition of those from whom he goes away. This is the second-best course, in the absence of the philosopher-king. And, as the Hellenic world will not listen to Plato's heroic remedy, he accom-

modates his counsel to their preconceptions. He returns *Laws*, once more from abstract discussions to study the application of ideas to life, and though, by the conditions of the problem, his course is "nearer earth and less in light," this long writing, which is said to have been posthumous,⁴ has a peculiar interest. The ripeness of accumulated experience and the mellowness of wise contemplation make up for the loss of prophetic insight and poetic charm.

The form of dialogue is still retained, and an aged Athenian is imagined as discoursing of legislation with the Lacedæmonian Megillus and the Cretan Clinias, who has in view the foundation of a new colony, and is on his way with his two companions from Cnossus to the temple and oracle of Zeus.

Plato now aims at moderating between Dorian and Ionian law, freely criticizing both, and refining on them from a higher point of view. "The praise of obedience, the authority assigned to elders, the prohibition of dowries, the enforcement of marriage, the common meals, the distribution and inalienability of land, the institution of the Crypteia, the freedom of bequest to a favourite son, the dislike of city walls—all reflect the custom of Sparta."

... "The use of the lot, the scrutiny of magistrates, the monthly courses of the council, the pardon of the forgiven homicide, most of the regulations about testaments and the guardianship of orphans, the degrees of consanguinity recognized by law, correspond to Athenian laws and customs" (Jowett).

The philosopher's own thoughts come out most strongly in the "preludes" to the laws,⁵ and in the regulations concerning education, marriage, and the punishment of impiety (i.e., 1st, atheism, 2d, denial of providence, 3d and worst, immoral superstition). The difficulty which is met in the *Politicus* by the abandonment of the world for a time, and in the *Timæus* by the lieutenantcy of lower gods, here leads to the hypothesis of an evil soul. The priority of mind (often before asserted) and the increased importance attached to numbers are the chief indications of Plato's latest thoughts about the intelligible world. But it must be remembered that the higher education (answering to *Rep.*, vi., vii.) is expressly reserved.⁶ Had Plato written his own *Epinomis*, the proportions of the whole work (not then "acephalous") might have been vastly changed.

The severity of the penalties attached to the three forms of heresy, especially to the third and worst of them, has led to the remark that Plato, after asserting "liberty of prophesying," had become intolerant and bigoted in his old age. But the idea of toleration in the modern sense was never distinctly present to the mind of any ancient philosopher. And, if in the *Laws* the lines of thought have in one way hardened, there are other ways in which experience has softened them. Plato's "second-best" constitution contains a provision, which was not admissible in the "perfect state," for possible changes and readaptations in the future. The power of self-reformation is hedged round indeed with extreme precautions; and no young or middle-aged citizen is ever to hear a word said in depreciation of any jot or tittle of the existing law. But that it should be provided, however guardedly, that select commissioners, after travelling far and wide, should bring back of the fruit of their observations for the consideration of the nocturnal council, and that a power of constitutionally

amending the laws should thus be admitted into the state, is sufficiently remarkable, when the would-be finality of ancient legislation is considered. Plato even comes near to the reflexion that "constitutions are not made, but grow" (iv. 709 A).

Plato in the *Laws* desists finally from impersonating Socrates. But he is in some ways nearer to his master in spirit than when he composed the *Phædrus*. The sympathy with common life, the acceptance of Greek religion, the deepening humanity, are no less essentially Socratic than the love of truth which breathes in every page. And some particular aspects of Socratism reappear, such as the question about courage¹ and that concerning the unity of virtue.²

Doubtful
and spu-
rious
works.

Of the dialogues forming part of the "Platonic canon," and not included in the preceding survey, the *Lesser Hippias*, *First Alcibiades*, and *Menæxenus* are the most Platonic, though probably not Plato's. The *Greater Hippias* and the *Clitophon* are also admitted to have some plausibility. The *Second Alcibiades* (on Prayer), the *Hipparchus* (touching on Pisistratus and Homer), *Minos* ("de lege"), *Epinomis*, *Erastæ*, *Theages*, are generally condemned, though most of them are very early forgeries or Academic exercises.³ And the *Asiarchus* (though sometimes prized for its subject, "the contempt of death"), the *De Justo*, *De Virtute*, *Demodocus*, *Sisyphus*, *Eryxias* (a not-uninteresting treatise on the use of money), together with the so-called *Definitions*, were rejected in ancient times, and are marked as spurious in the MSS.

Two great forces are persistent in Plato, the love of truth and zeal for human improvement. In the period culminating with the *Republic*, these two motives, the speculative and the practical, are fused in one harmonious working. In the succeeding period, without excluding one another, they operate with alternate intensity. In the varied outcome of his long literary career, the metaphysical "doctrine of ideas" which has been associated with Plato's name underwent many important changes. But pervading all of these there is the same constant belief in the supremacy of reason and the identity of truth and good. From that abiding root spring forth a multitude of thoughts concerning the mind and human things,—turning chiefly on the principles of psychology, education, and political reform,—thoughts which, although unverified, and often needing correction from experience, still constitute Plato the most fruitful of philosophical writers. While general ideas are powerful for good or ill, while abstractions are necessary to science, while mankind are apt to crave after perfection, and ideals, either in art or life, have an acknowledged value, so long the renown of Plato will continue. "All philosophic truth is Plato rightly divined; all philosophic error is Plato misunderstood"—is the verdict of one of the keenest of modern metaphysicians.⁴

Plato's followers, however, have seldom kept the proportions of his teaching. The diverse elements of his doctrine have survived the spirit that informed them. The Pythagorizing mysticism of the *Timæus* has been more prized than the subtle and clear thinking of the *Theætetus*. Logical inquiries have been hardened into a barren ontology. Semi-mythical statements have been construed literally, and mystic fancies perpetuated without the genuine thought which underlay them. A part (and not the essential part) of his philosophy has been treated as the whole. But the influence of Plato has extended far beyond the limits of the Platonic schools. The debt of

Aristotle to his master has never yet been fully estimated. Zeno, Chrysippus, Epicurus borrowed from Plato more than they knew. The moral ideal of Plutarch and that of the Roman Stoics, which have both so deeply affected the modern world, could not have existed without him. Neopythagoreanism was really a crude Neoplatonism. And the Sceptics availed themselves of weapons either forged by Plato or borrowed by him from the Sophists. A wholly distinct line of infiltration is suggested by the mention of Philo and the Alexandrian schools, and of Clement and Origen, while Gnostic heresies and even Talmudic mysticism betray perversions of the same influence. The effect of Hellenic thought on Christian theology and on the life of Christendom is a subject for a volume, and has been pointed out in part by Professor E. Zeller and others (comp. NEOPLATONISM). Yet when Plotinus in the 3d century (after hearing Ammonius), amidst the revival of religious paganism, founded a new spiritualistic philosophy upon the study of Plato and Aristotle combined, this return to the fountain-head had all the effect of novelty. And for more than two centuries, from Plotinus to Proclus, the great effort to base life anew on the Platonic wisdom was continued. But it was rather the ghost than the spirit of Plato that was so "unsphered." Instead of striving to reform the world, the Neoplatonist sought after a retired and cloistered virtue. Instead of vitalizing science with fresh thought, he lost hold of all reality in the contemplation of infinite unity. He had some skill in dealing with abstractions, but laid a feeble hold upon the actual world.

"Hermes Trismegistus" and "Dionysius Areopagita" are names that mark the continuation of this influence into the Middle Ages. The pseudo-Dionysius was translated by Erigena in the 9th century.

Two more "Platonic" revivals have to be recorded,—at Florence in the 15th and at Cambridge in the 17th century. Both were enthusiastic and both uncritical. The translation of the dialogues into Latin by Marsiglio Ficino was the most lasting effect of the former movement, which was tinged with the unscientific ardour of the Renaissance. The preference still accorded to the *Timæus* is a fair indication of the tendency to bring *fumum ex fulgore* which probably marred the discussions of the Florentine Academy concerning the "chief good." The new humanism had also a sentimental cast, which was alien from Plato. Yet the effect of this spirit on art and literature was very great, and may be clearly traced not only in Italian but in English poetry.

"The Cambridge Platonists" have been described by Principal Tulloch in his important work on *Rational Theology in England in the 17th Century*. Their views were mainly due to a reaction from the philosophy of Hobbes, and were at first suggested as much by Plotinus as by Plato. It is curious to find that, just as Socrates and Ammonius (the teacher of Plotinus) left no writings, so Whichcote, the founder of this school, worked chiefly through conversation and preaching. His pupils exercised a considerable influence for good, especially on English theology; and in aspiration if not in thought they derived something from Plato, but they seem to have been incapable of separating his meaning from that of his interpreters, and Cudworth, their most consistent writer, was at once more systematic and less scientific than the Athenian philosopher. The translations of Sydenham and Taylor in the 18th century and the beginning of the 19th are proofs of the continued influence of Platonism in England.

The critical study of Plato begins from Schleiermacher, who did good work as an interpreter, and tried to arrange the dialogues in the order of composition. His attempt, which, like many efforts of constructive criticism, went far

¹ Comp. *Laches*.

² Comp. *Protagoras*.

³ According to Schaarschmidt, only nine dialogues are genuine,—*Protag.*, *Phædr.*, *Symp.*, *Apol.*, *Cratyl.*, *Phædo.*, *Rep.*, *Tim.*, *Leges*.

⁴ Ferrier, *Institutes of Metaphysics*, p. 169 (sect. I., prop. vi. § 12).

beyond possibility, was vitiated by the ground-fallacy of supposing that Plato had from the first a complete system in his mind which he partially and gradually revealed in writing. At a considerably later time Karl Friedrich Hermann, to whom all students of Plato are indebted, renewed the same endeavour on the far more plausible assumption that the dialogues faithfully reflect the growth of Plato's mind. But he also was too sanguine, and exaggerated the possibility of tracing a connexion between the outward events of Plato's life and the progress of his thoughts. This great question of the order of the dialogues, which has been debated by numberless writers, is one which only admits of an approximate solution. Much confusion, however, has been obviated by the hypothesis (first hinted at by Ueberweg, and since supported by the present writer and others) that the *Sophistes* and *Politicus*, whose genuineness had been called in question by Socher, are really intermediate between the *Republic* and the *Laws*. The allocation of these dialogues, and consequently of the *Philebus*, not only on grounds of metaphysical criticism, but also on philological and other evidence of a more tangible kind, supplies a point of view from which it becomes possible to trace with confidence the general outlines of Plato's literary and philosophical development. Reflecting at first in various aspects the impressions received from Socrates, he is gradually touched with an inspiration which becomes his own, and which seeks utterance in half-poetical forms. Then first the ethical and by and by the metaphysical interest becomes predominant. And for a while this last is all absorbing, as he confronts the central problems which his own thoughts have raised. But, again, the hard-won acquisitions of this dialectical movement must be fused anew with imagination and applied to life. And in a final effort to use his intellectual wealth for the subvention of human need the great spirit passed away.

EDITIONS.—Aldine (fol., Ven., 1513); H. Stephanus (Lausanne, 1587). *Separate Dialogues*.—Timæus (Gr. and Lat., Chalcedius, 1579; repr. by Wrobel, Leips., 1876). *German and Dutch*.—Tiedemann (Zweibrücken, 1781-87); Bekker (with v. II., Berlin, 1816-17-23; London, 1826); Stallbaum (crit. ed., Leips., [1821] 1825; text, [1850] 1874; ed. major, Götting., [1827] 1880; ed. major, partly re-edited by Wöhrlab, [1877] 1882); Baiter-Orelli-Winkelmann (Zurich, [1839] 1881); Engelmann (with Germ. trans. and comm., [1841] 1877); K. F. Hermann (Leips., 1851-53 and 1868-74); Wöhrlab (see Stallbaum, 1877); Martin Schanz (1875-81, not yet completed); L. F. Heindorf (*Lys.*, *Charm.*, *Hipp. Maj.*, *Phædr.*, *Gorg.*, *Theæt.*, *Crat.*, *Parm.*, *Euthyd.*, *Prot.*, *Soph.*, 1802-10); F. Ast (*Protag.*, *Phædr.*, *Gorg.*, *Phædo*, with comm., 1819-22). *Separate Dialogues*.—*Symposium*, by F. A. Wolf ([1782] 1828) and Otto Jahn ([1864] 1875); *Republic*, by Ast ([1804] and Schneider ([1830] 1833); *Phædo*, by Wyttenbach (1810); *Legg. et Epinomis*, by Ast (Leips., 1814); *Parmenides*, by Stallbaum (1839); *Philebus*, by Stallbaum (1840); *Critias*, by Schneider (Wrocław, 1855); *Timæus* (Chalcedius, 1569; repr. by Wrobel, Leips., 1876); and *Gorg.*, by Krohn. *English*.—*Timæus* (Gr. and Lat., Camb., 1670); *De rebus divinis dialogi selecti* (Camb., 1673); *Euthyd.*, *Gorg.* (cum notis), by Routh (Camb., 1784); *Protag.*, by Wayte ([1854] 1871); *Philebus*, by Badham (Lond., [1855] 1878) and Poste (1860); *Theæt.*, by L. PLATON, LEVSHIN (1737-1812), a celebrated Russian archbishop, was born at the village of Tchashnikovo, near Moscow, in 1737, and was educated in the academy of that city. On completing his studies there in 1758 he was appointed teacher of rhetoric in the school connected with the monastery of St Sergius, and about this time entered the priesthood. In 1763 Catherine invited him to instruct her son Paul in theology, and he became one of the court chaplains. Three years afterwards Platon was appointed archimandrite of the monastery of the Trinity (Troitzkaia Lavra) near Moscow; in 1770 he was made archbishop of Tver, and finally in 1787 archbishop of Moscow and metropolitan. He died in 1812. Platon was a brilliant and learned man, not only in the opinion of his countrymen, but in the estimation of all foreigners who made his acquaintance. We get a graphic and interesting picture

of him at the beginning of the present century in the travels of Edward Clarke of Cambridge, who was much struck with his wit and wide range of reading. As a preacher he enjoyed great celebrity, one of the most remarkable specimens of his eloquence being the sermon preached at the coronation of Alexander I. He was also the author of several works which enjoyed considerable reputation in their time, such as *A Short Course of Divinity*, compiled for the use of the emperor Paul when grand-duke, several *Catechisms*, *A Short History of the Russian Church*, which has been translated into English, and other works. Platon is altogether a striking and important figure in a very eventful period of his country's history.

PLATTNER, CARL FRIEDRICH (1800-1858), a famous scientific metallurgist, was born in Kleinwaltersdorf, near Freiberg in Saxony, on the 2d January 1800, and died

in the latter town on the 22d January 1858. Plattner's father, though only a poor working miner, found the means for having his son educated first at the "Bergschule" and then at the "Bergakademie" of Freiberg. After having completed his curriculum there in 1820, he obtained a position in connexion with the royal mines and metal works, and was employed chiefly as an assayer, in which capacity he soon became conspicuous by his rare exactness and circumspection, and his constant striving after scientific advancement.

The mouth-blowpipe, after doing service for centuries to metal-workers as a soldering tool (hence the German name *Löthrohr*), in the hands of Gahn and subsequently of Berzelius became the most useful of instruments for the qualitative testing of mineral substances. Through the efforts of the latter, in fact, blowpipe analysis had developed into almost an independent branch of analysis. But nobody dreamt of quantitative mouth-blowpipe assaying until Harkort in 1827 (while a student in the Freiberg academy) succeeded in working out a blowpipe-assay for silver. Harkort stopped there; but the idea of blowpipe-assaying was taken up subsequently by Plattner, who, by bringing his characteristic thoroughness, indefatigability, and unexampled dexterity to bear on the subject, succeeded in working out reliable methods for all the ordinary useful metals. His modes of assaying for cobalt and nickel more especially quickly found favour with metallurgists, because they were more exact than the then known corresponding methods of "wet-way" analysis, and required a less number of hours than the latter required of days for their execution. Our analytical methods for the determination of cobalt have since become far more perfect but no less troublesome, and to the present day Plattner's nickel-assay is the most precise method for the estimation of this metal in complex mixtures.

Plattner, while working at this specialty of his own, at the same time overhauled the entire field of qualitative blowpipe assaying, and ultimately summed up the whole of his vast experience in his *Probirkunst mit dem Löthrohr*, which soon became, and to the present day ranks as, the standard book on the subject. Since its first publication in 1835 the work has gone through four editions, apart from two independent English translations.

With all his high and recognized distinction in his own specialty, Plattner most keenly felt that his scientific education in Freiberg had been somewhat one-sided; and in 1839 he left his post and family to work for a year in Heinrich Rose's laboratory in Berlin, and supplement his knowledge of modern methods of chemical analysis. While there as a student he at the same time acted as a teacher in his branch, and won the lasting friendship of a number of distinguished scientific men. On his return home in 1840 he was raised to the rank of assessor at the Government board of mining and metallurgy, and made chief of the royal department of assaying. In 1842 he was deputed to complete a course of lectures on metallurgy in the Bergakademie which had been commenced by Lampadius; and he subsequently became Lampadius's successor as professor of that branch, and for the then newly instituted course of blowpipe-assaying. In addition to these functions he instituted, in 1851, a special course on the metallurgy of iron. He continued lecturing in the academy as long as he was able,—until the session of 1856–57. It was during this period of professorial activity that he made the extensive studies and experimental researches which form the basis of his work *Die metallurgischen Röstprocesse theoretisch betrachtet* (Freiberg, 1856). His well-known *Vorlesungen über allgemeine Hüttenkunde* (vol. i. and ii., Freiberg, 1860) is a posthumous publication edited by Prof. Thomas Richter.

In addition to these great works (and the *Probirkunst*) Plattner published (in *Erdmann's Journal* and in *Schweigger's Journal* and elsewhere) numerous memoirs on metallurgical or mineralogical subjects, regarding which we must confine ourselves to saying that they mark him as an investigator of rare diligence and power. How he found time for all his original work is difficult to say; it certainly did not cause him to neglect his students. He attended to them in the most conscientious and efficient manner, as hundreds of his pupils all over the world can testify. His marked success as a teacher was no doubt owing greatly to his high personal qualities,—his cheerful, untiring, unselfish devotion to duty, his kindness of heart and manner, his freedom from all cant and morbid ambition. The latter years of his life were embittered by intense suffering. After a long period of lingering illness he succumbed to a disease of the brain.

PLATTSBURGH, a village and township of the United States, the shire-town of Clinton county, New York, and the port of entry of Champlain customs district, lies on the west side of Lake Champlain at the mouth of the Saranac. By rail it is 168 miles north of Albany and 73 south-south-east of Montreal (Canada). A branch line runs 20 miles south-west to Au Sable and forms a favourite route to the Adirondacks, and the Chateaugay Railroad runs 34 miles west by north to Lyon Mountain, where there are extensive iron mines. Plattsburgh contains county buildings and court-house, a custom-house, a high school, and a small public library. It has nail and waggon factories, flour-mills, saw-mills, an iron furnace, machine shops, and a large sewing-machine manufactory. It is a garrison town of the United States army, with extensive barracks about a mile south of the village. The value of the imports and exports of the district for the year ending June 30th 1884 was \$3,169,780 and \$1,319,422; and 1279 vessels entered from Canada, while 1179 cleared. The aggregate burthen of the vessels belonging to the district was 57,477 tons. In 1870 the township had 8414 inhabitants, the village 5139; in 1880 the figures were 8283 and 5245.

Plattsburgh dates from 1785. It has twice been destroyed by fire (1849 and 1867). In 1812 it became the headquarters of the U.S. army on the northern frontier; and in September 1814 it was rendered famous through the capture of the British flotilla under Commodore Downie by the United States flotilla under Commodore Macdonough, and the consequent retreat across the Saranac of Sir George Prevost, who had been attacking the village with a powerful army. Downie and fifteen other officers of the contending forces are buried in Plattsburgh cemetery.

PLATYPUS. The Duck-billed Platypus (*Platypus anatinus*) was the name assigned to one of the most remarkable of known animals by Shaw, who had the good fortune to introduce it to the notice of the scientific world in the *Naturalist's Miscellany* (vol. x., 1799). In the following year it was independently described by Blumenbach (*Voigts Magazin*, ii. p. 205) under the name of *Ornithorhynchus paradoxus*. Shaw's generic name, although having priority to that of Blumenbach, could not be retained, as it had been used at a still earlier time (1793) by Herbst for a genus of *Coleoptera*. *Ornithorhynchus* is therefore now universally adopted as the scientific designation, although Duck-billed Platypus may be conveniently retained as a vernacular appellation. By the colonists it is called "Water-Mole," but its affinities with the true moles are of the slightest and most superficial description.

The anatomical differences by which the platypus, and its only ally the echidna, are separated from all other mammals, so as to form a distinct subclass with relationship to the inferior vertebrated classes, have been described in the article MAMMALIA (vol. xv. pp. 371 and 377), where

also will be found the main distinctive characters of the two existing representatives of the group. It is there stated that the early stages of the development of the young are not yet fully known; in fact this was till very recently one of the most interesting problems in zoology to be solved. It has been repeatedly affirmed, in some cases by persons who have had actual opportunities of observation, that the platypus lays eggs; but these statements have been generally received with scepticism and even denial. This much-vexed question has, however, been settled by the researches of Mr W. H. Caldwell (1884), who has found that these animals, although undoubtedly mammals throughout the greater part of their structure, are oviparous, laying eggs, which in the manner of their development bear a close resemblance to the development of those of the *Reptilia*. Two eggs are produced at a time, each measuring about three-fourths of an inch in its long and half an inch in its short axis, and enclosed in a strong, flexible, white shell.

The platypus is pretty generally distributed in situations suitable to its aquatic habits throughout the island of Tasmania and the southern and eastern portions of Australia. Slight variations in the colouring and size of different individuals have given rise to the idea that more

Platypus. From Gould's *Mammals of Australia*.

than one species may exist; but all naturalists who have had the opportunity of investigating this question by the aid of a good series of specimens have come to the conclusion that there is but one; and no traces of any extinct allied forms have yet been discovered.

The length of the animal when full grown is from 18 to 20 inches from the extremity of the beak to the end of the tail, the male being slightly larger than the female. The fur is short, dense, and rather soft to the touch, and composed of an extremely fine and close under-fur, and of longer hairs which project beyond this, each of which is very slender at the base, and expanded, flattened, and glossy towards the free end. The general colour is deep brown, but paler on the under parts. The tail is short, broad, and depressed, and covered with coarse hairs, which in old animals generally become worn off from the under surface. The eyes are small and brown. There is no projecting pinna or ear-conch. The mouth, as is well known, bears a striking resemblance to the bill of a duck. It is covered with a naked skin, a strong fold of which projects outwards around its base. The nostrils are situated near the extremity of the upper surface. There are no true teeth, but their purposes are served by horny prominences,

two on each side of each jaw,—those in the front narrow, longitudinal, sharp-edged ridges, and those behind broad, flattened, and molariform. The upper surface of the lateral edges of the mandible has also a number of parallel fine transverse ridges, like those on the bill of a duck. In the cheeks are tolerably capacious pouches, which appear to be used as receptacles for food.

The limbs are strong and very short, each with five well-developed toes provided with strong claws. In the fore feet the web not only fills the interspaces between the toes, but extends considerably beyond the ends of the long, broad, and somewhat flattened nails, giving great expanse to the foot when used for swimming, though capable of being folded back on the palm when the animal is burrowing or walking on the land. On the hind foot the nails are long, curved, and pointed, and the web extends only to their base. On the heel of the male is a strong, curved, sharply pointed, movable horny spur, directed upwards and backwards, attached by its expanded base to the accessory bone of the tarsus. This spur, which attains the length of nearly an inch, is traversed by a minute canal, terminating in a fine longitudinal slit near the point, and connected at its base with the duct of a large gland situated at the back part of the thigh. The whole apparatus is so exactly analogous in structure to the poison gland and tooth of a venomous snake as to suggest a similar function, but evidence that the platypus ever employs its spur as an offensive weapon has, at all events until lately, been wanting. A case is, however, related by Mr Spicer in the *Proceedings* of the Royal Society of Tasmania for 1876 (p. 162) of a captured platypus inflicting a severe wound by a powerful lateral and inward movement of the hind legs, which wound was followed by symptoms of active local poisoning. It is not improbable that both the inclination to use the weapon and the activity of the secretion of the gland may be limited to the breeding season, and that their purpose may be, like that of the antlers of deer and many similar organs, for combat among the males. In the young of both sexes the spur is present in a rudimentary condition, but it disappears in the adult females.

The platypus is aquatic in its habits, passing most of its time in the water or close to the margin of lakes and streams, swimming and diving with the greatest ease, and forming for the purpose of sleeping and breeding deep burrows in the banks, which generally have two orifices, one just above the water level, concealed among long grasses and leaves, and the other below the surface. The passage at first runs obliquely upwards in the bank, sometimes to a distance of as much as 50 feet, and expands at its termination into a cavity, the floor of which is lined with dried grass and leaves, and in which the eggs are laid and the young brought up. Their food consists of aquatic insects, small crustaceans, and worms, which are caught under water, the sand and small stones at the bottom being turned over with their bills to find them. They appear at first to deposit what they have thus collected in their cheek pouches, and when these are filled they rise to the surface and quietly triturate their meal with the horny teeth before swallowing it. Swimming is effected chiefly by the action of the broad forepaws, the hind feet and tail taking little share in locomotion in the water. When asleep they roll themselves into a ball, as shown in the figure. In their native haunts they are extremely timid and wary, and very difficult to approach, being rarely seen out of their burrows in the daytime. Mr A. B. Crowther, who has supplemented the often quoted observations of Dr George Bennett upon the habits of these animals in confinement, says, "They soon become very tame in captivity; in a few days the young

ones appeared to recognize a call, swimming rapidly to the hand paddling the water; and it is curious to see their attempts to procure a worm enclosed in the hand, which they greedily take when offered to them. I have noticed that they appear to be able to smell whether or not a worm is contained in the closed hand to which they swim, for they desisted from their efforts if an empty fist was offered." When irritated they utter a soft low growl, resembling that of a puppy. (W. H. F.)

PLAÜEN, a busy manufacturing town of Saxony, in the government district of Zwickau, is situated on the Elster, 60 miles to the south of Leipsic. It was formerly the capital of the Voigtland, a territory governed directly by the imperial voights or bailiffs, and this name still clings in popular speech to the hilly manufacturing district in which it lies. The most prominent buildings are the fine Gothic church of St John, the town-house (about 1550), the new post-office, and the loftily-situated old castle of Hradschin, now occupied by a law court. Plauen is now the chief place in Germany for the manufacture of embroidered white goods of all kinds, and for the finishing of woven cotton fabrics. Dyeing, tanning, bleaching, and the making of paper and machinery are also prosecuted; and an active trade is carried on in these various industrial products. In 1880 the town contained 35,078 inhabitants and in 1884 above 40,000, almost all Protestants.

As indicated by the name of the castle, Plauen was probably founded by the Slavs, after whose expulsion it was governed directly by the imperial bailiffs. In 1327 it became a Bohemian fief, but passed into the possession of Saxony in 1466 and remained permanently united to it from 1569 onwards. The manufacture of white goods was introduced by Swabian or Swiss immigrants about 1570, and since then the prosperity of the town has been great, in spite of the storms of the Thirty Years' and Seven Years' Wars. The advance of Plauen has been especially rapid since its incorporation in the Zollverein.

PLAUTUS, T. MACCIUS, was the greatest comic and dramatic genius of Rome, and still ranks among the great comic dramatists of the world. While the other creators of Roman literature, Nævius, Ennius, Lucilius, &c., are known to us only in fragments, we still possess twenty plays of Plautus. A few of them are incomplete, and in some cases they show traces of later interpolations, but they have reached us in the main as they were written by him in the end of the 3d and the beginning of the 2d century B.C. At the date of his birth Roman literature may be said to have been non-existent. When he died the Latin language had developed its full capacities as an organ of social intercourse and familiar speech, and the literature of the world had been enriched by a large number of adaptations from the New Comedy of Athens, animated by the new life of ancient Italy and vivified by the genius and robust human nature of their author; and these have been the chief means of transmitting the traditions of the ancient drama to modern times. The maturity which comedy attained in a single generation affords a remarkable contrast to the slow processes by which the higher forms of Roman poetical and prose literature were brought to perfection. It may be explained partly by the existence, for some generations before the formal beginning of literature at Rome, of the dramatic and musical medleys ("saturæ impletæ modis") which in their allusions to current events and their spirit of banter must have had a considerable affinity with the dialogue of Plautus, and partly to the diffusion of the Latin language, as the organ of practical business among the urban communities of Italy. But much also was due to the individual genius and the command over their native idiom possessed by the two oldest of the genuine creators of Roman literature, Nævius and Plautus.

A question might be raised as to whether Plautus or

his younger contemporary Ennius was the most characteristic representative of the national literature of their time. Ennius certainly exercised a much more important influence on its subsequent development. He arrested the tendency imparted to that development by Nævius and Plautus. He made literature the organ of the serious spirit and imperial ambition of the Roman aristocracy, while the genius of Plautus appealed to the taste and temperament of the mass of the people, at a time when they were animated by the spirit of enjoyment and comparatively indifferent to political questions. The ascendancy of the aristocracy in public affairs for two generations after the end of the Second Punic War determined the ascendancy of Ennius in Roman literature; and it may be admitted that, if the genius of Plautus and of Ennius could not work harmoniously together, it was best that that of the younger poet, as representative of the truer genius of Rome, should prevail. The popularity of Plautus was greatest in his own time and in the generation succeeding him, but his plays still continued to be acted with applause till the age of Cicero, and he was greatly admired both by Cicero and by the man among his contemporaries who, both from his learning and taste, retained most of the antique spirit, Varro. The literary taste of the Augustan age and of the first century of the empire was adverse to him; but the archaic revival in the latter part of the 2d century of our era brought him again into favour, with the result of securing the preservation of his works through mediæval times and their revival with great acceptance at the Renaissance. That his original popularity was due to genuine gifts of humour and genuine power in representing human life is clear from their reception by a world so much altered from that in which he himself had played his part. And if his influence was not felt like that of Ennius in determining the form and spirit of the literature of his country, it was not without effect on the two greatest dramatists of modern times, Shakespeare and Molière.

The few facts known of his life rest on the authority of Cicero, of Aulus Gellius, and of Jerome in his continuation of the Eusebian *Chronicle*. He was born in the earlier half of the 3d century B.C., and died at an advanced age in the year 184 B.C. He was a native of Sarsina in Umbria. His first employment was in some way connected with the stage "in operis artificum scenicorum." He saved money in this employment, engaged in foreign trade, and returning to Rome in absolute poverty was reduced to work as a hired servant in a mill; and then for the first time he began to write comedies. The earliest allusion to any contemporary event which we find in any of his plays is that in the *Miles Gloriosus* (l. 212-3) to the imprisonment of Nævius, which happened about the year 207 B.C. The *Cistellaria* and *Stichus* were apparently written immediately after the end of the Second Punic War. The last ten years of his life were the most productive, and the greater number of his extant comedies belong to that period. They do not seem to have been published as literary works during his lifetime, but to have been left in possession of the players, to whom the interpolations and some other unimportant changes are to be ascribed. The prologues to the plays, with three or four exceptions, belong to the generation after his death. In a later age the plays of many contemporary playwrights were attributed to him. Twenty-one were accepted by Varro as undoubtedly genuine, and of these we possess twenty nearly complete, and fragments of another, the *Vidularia*. Other nineteen Varro regarded as probably genuine, and the titles of some of them, e.g., *Saturio*, *Addictus*, *Com-morientes*, are also known to us.

We get the impression from his works and from ancient

criticisms on them that he was, in his latter years, a rapid and productive writer, more concerned with the immediate success of his works than with their literary perfection.¹ Yet he shows that he took pride and pleasure in his art (*Bacch.*, 214), and Cicero testifies especially to the gratification which he derived from two works of his old age, the *Pseudolus* and *Truculentus* (*De Senec.*, 14). We get further the impression of a man of strong animal spirits and of large intercourse with the world, especially with the trading and middle classes. We find no indication of familiarity with the manners, tastes, or ideas of the governing aristocracy. The story told of his unsuccessful mercantile speculations might seem to derive confirmation from the "flavour of the sea" and the spirit of adventure present in many of his plays, from his frequent colloquial use of Greek phrases, and from indications of familiarity with the sights, manners, and pleasures of the Greek cities on the Mediterranean. He has many allusions to works of art, to the stories of Greek mythology, and to the subjects of Greek tragedies; and he tried to enrich the native vocabulary with a considerable number of Greek words which did not maintain their place in the language. The knowledge of these subjects which he betrays, and his copious use of Greek words and phrases, seem to be the result rather of active and varied intercourse with contemporary Greeks than of the study of books.

Like all the old Roman dramatists, he borrows his plots, incidents, scenes, characters, and probably the outlines of his dialogue from the authors of the new comedy of Athens,—Diphilus, Philemon, Menander, and others. But he treated his borrowed materials with much more freedom and originality than the only other dramatist of whom we possess complete pieces—Terence. A note of this difference appears in the fact that the titles of all the plays of Terence are Greek, while those of Plautus are nearly all Latin. We find a much greater range and variety in the scenes and incidents introduced by Plautus, and much greater divergence from a conventional type in his characters. But it is especially on his dialogue and his metrical soliloquies that his originality is stamped. Though all the personages of his plays are supposed to be Greeks, living in Greek towns, they constantly speak as if they were Romans living in the heart of Rome. Frequent mention is made of towns in Italy, of streets, gates, and markets in Rome itself, of Roman magistrates and of their duties, of the business of the law-courts, the comitia, and the senate, &c. We constantly meet with Roman formulæ, expressions of courtesy, proverbs, and the like. While avoiding all direct reference to politics, he frequently alludes to recent events in Roman history, and to laws of recent enactment. Although he maintains and seems to inculcate an attitude of political indifference, he is not altogether indifferent to social conditions, and in more than one of his plays comments on the growing estrangement between the rich and poor, as an element of danger to the state. Still he writes neither as a political nor as a social satirist, but simply with the wish to represent the humours of human life and to amuse the people in their holiday mood.

His independence of his originals, in regard to expression, is further shown by the puns and plays on words, the alliterations, assonances, &c., which do not admit of being reproduced in translation from one language to another; in the metaphors taken from Roman military operations, business transactions, and the trade of various artisans; and in his profuse use of terms of endearment and vituperation, characteristic of the vivacity of the Italian temperament in modern as in ancient times. But in nothing is his difference from Terence, and presum-

ably from the originals which they both followed, more decided than in his large use of lyrical monologue, or "cantica," alternating with the ordinary dialogue in much the same way as the choral odes do in the old Greek comedy. These one may conjecture to have been a partial survival of passages in the old dramatic *saturæ*, which were repeated to a musical accompaniment. In the naïveté of the reflexions which they contain, and the proximity with which the thought is worked out, we recognize the earliest effort of the Roman mind applied to reflexion on life, and no reproduction of any phase of the Greek mind to which the expression of such reflexion had been familiar for generations.

In the diction of Plautus accordingly we may consider that we have a thorough reflexion of his own mind, and an important witness of Roman life and thought in his time. The characters in his plays are the stock characters of the New Comedy of Athens, the "fallax servus," the "leno insidiosus," the "meretrix blanda," the "parasitus edax," the "amans ephebus," the "pater attentus," &c. We may miss the finer insight into human nature and the delicate touch in drawing character which Terence presents to us in his copies from Menander, but there is wonderful life and vigour, and considerable variety in the embodiment of these different types by Plautus. The characters of Ballio and Pseudolus, of Euclio in the *Aulularia*, of the two Menæchmi, and of many others have a real individuality, which shows that in reproducing Greek originals Plautus thoroughly realized them and animated them with the strong human nature of which he himself possessed so large a share. For his plots and incidents he has been much more indebted to his originals. There is a considerable sameness in many of them. A large number turn upon what are called "frustrationes"—tricks by which the slave who plays the principal part in the comedy succeeds in extracting either from the father of his young master or from some other victim a sum of money to aid his master in his love affairs. But Plautus, if not more original, is more varied than Terence in his choice of plots. In some of them the passion of love plays either no part or a subordinate one. He also varies his scenes much more than Terence. Thus in some of his plays we find ourselves at Epidamnus, at Ephesus, at Cyrene, and not always in Athens.

The following is a list of the comedies according to their usual arrangement, which is nearly, but not strictly alphabetical:—*Amphitruo*, *Asinaria*, *Aulularia*, *Captivi*, *Curculio*, *Casina*, *Cistellaria*, *Epidicus*, *Bacchides*, *Mostellaria*, *Menæchmi*, *Miles Gloriosus*, *Mercator*, *Pseudolus*, *Pænulus*, *Persa*, *Rudens*, *Stichus*, *Trinummus*, *Truculentus*. Of these the most generally read, and on the whole the most interesting, are the *Aulularia*, *Captivi*, *Menæchmi*, *Miles Gloriosus*, *Mostellaria*, *Pseudolus*, *Rudens*, and *Trinummus*. Besides these the *Amphitruo*, *Bacchides*, and *Stichus* (although the last two are incomplete) are of special interest. The *Amphitruo* is altogether exceptional, and gives, perhaps, as high an idea both of the comic and of the imaginative power of the author as any of the others. The interest attaching to it is enhanced by the fact that it has been imitated both by Molière and Dryden, that attaching to the *Aulularia* by its having suggested the subject of *L'Avare* of the French dramatist, and to the *Menæchmi* by the reappearance of its principal motive in the *Comedy of Errors* of Shakespeare. The *Captivi* was characterized by Lessing as the best constructed drama in existence. It may be classed with the *Rudens* as appealing to a higher and purer class of feelings, and as coming nearer to the province of serious poetry, than any other extant specimens of Latin comedy. The *Aulularia* and *Trinummus* may be mentioned along with these as bringing us into contact with characters more estimable and attractive than those in the great majority of the other pieces.

While there are abundant good sense and good humour in the comedies of Plautus, and occasional touches of pathos and elevated feeling in one or two of them, there is no trace of any serious purpose behind his humorous scenes and representations of character. He presents a remarkable exception to the didactic and moralizing spirit which appears in most of the leading representatives of Roman literature. He is to be judged on the claim

¹ "Securus cadat an recto stet fabula talo."—Hor. *Ep.* ii. 1, 176.

which is put forward in the epitaph which in ancient times was attributed to himself :—

"Postquam est mortem aptus Plautus, comœdia luget,
Scœna est deserta, dein risus, ludu' jocusque,
Et numeri innumeri simul omnes conlacrumarunt."¹

He has not the more subtle and penetrating irony which we recognize in Terence, in Horace, and in Petronius; still less can we attribute to him the "rigidi censura cachinni" which accompanied and inspired the humorous fancies of Lucilius and Juvenal. But among all the ancient humorists, with the exception of Aristophanes, he must have had the power of immediately provoking the heartiest and broadest mirth and laughter. He was too careless in the construction of his plots to be a finished dramatic artist. He was apparently more popular among the mass of his countrymen than any Roman author of any age; but to be thoroughly popular he had to satisfy the tastes of an audience accustomed to the indigenous farces of Italy. This is the defect, according to the judgment of educated critics in the Augustan age, which Horace indicates in the line

"Quantus sit Dossennus edacibus in parasitis."

But he had the most wonderful power of dramatic expression of feeling, fancy, and character by means of action, rhythm, and language. In the line in which Horace expresses the more favourable criticism of his time,—

"Plautus ad exemplar Siculi properare Epicharmi,"—

the term *properare* expresses the vivacity of gesture, dialogue, declamation, and recitative in which the plays of Plautus never fail, and which must have made them admirable vehicles for the art of the actor. The lyrical recitative occupies a much larger place in his comedies than in those of Terence, and in them he shows the true poetical gift of adapting and varying his metres in accordance with the moods and fancies of his characters. But the gift for which he is pre-eminent above almost every other Roman author is the vigour and exuberant flow of his language. No other writer enables us to feel the life and force of the Latin idiom, undisguised by the mannerisms of a literary style, in the same degree. Among the masters of expression in which the prose and poetical literature of Rome abounds, none was more prodigally gifted than Plautus, and this gift of expression was the accompaniment of the exuberant creativeness of his fancy and of the strong vitality and lively social nature which was the endowment of the race to which he belonged.

In the beginning of the 15th century only the first eight plays (from *Amphitruo* to *Epidicus*) were in circulation. The other twelve were recovered in the course of that century, and two new manuscripts, one of them containing the whole twenty, were discovered in the following century. The Ambrosian palimpsest, discovered in 1815, has been recognized as the most trustworthy text for those plays which it preserves, and it is on this that the critical labours of Ritschl have been based. His great critical edition is being continued by his pupils G. Loewe, G. Götz, Fr. Schoell. An edition of the plays with a commentary by Professor Ussing of Copenhagen is now nearly complete. The most useful editions of separate plays are those of Lorenz and Brix. (W. Y. S.)

PLAYFAIR, JOHN (1748–1819), mathematician and physicist, was born at Benvie, Forfarshire, where his father was parish minister, on March 10, 1748. He was educated at home until the age of fourteen, when he entered the university of St Andrews. Ability for scientific studies must have appeared very early with him, for while yet a student he was selected to teach natural philosophy during the occasional absence of the professor. In 1766, when only eighteen, he was candidate for the chair of mathematics in Marischal College, Aberdeen, and, although he was unsuccessful, his claims were admitted to be high. Six years later he made application for the chair of natural philosophy in his own university, but again without success, and in 1773 he was offered and accepted the living of the united parishes of Liff and Benvie, vacant by the death of his father. He continued, however, to carry on his mathematical and physical studies, and in 1782 he resigned his charge in order to become the tutor of Ferguson of Raith. By this arrangement he was able to be frequently in Edinburgh, and to cultivate the literary and scientific society for which it was at that time specially distinguished; and through Maskelyne, whose acquaintance he had first made in the course of the celebrated Schiehallion experiments in 1774, he also gained access to the scientific circles of London. In 1785 when Dugald Stewart succeeded Ferguson in the Edinburgh chair

of moral philosophy, Playfair succeeded the former in that of mathematics. In 1802 he published a volume entitled *Illustrations of the Huttonian Theory of the Earth*, and in 1805 he exchanged the chair of mathematics for that of natural philosophy in succession to Robison, whom also he succeeded as general secretary to the Royal Society of Edinburgh. He took a prominent part, on the liberal side, in the ecclesiastical controversy which arose in connexion with Leslie's appointment to the post he had vacated, and published a satirical *Letter* (1806) which was greatly admired by his friends. His election as a fellow of the Royal Society took place in 1807. In 1815, after the establishment of a European peace, he made a journey through France and Switzerland to Italy, and remained abroad for nearly eighteen months, interesting himself chiefly in the geology and mineralogy of the districts he visited. After a few years of gradually failing health he died on July 19, 1819.

A collected edition of Playfair's works, with a memoir by James G. Playfair, appeared at Edinburgh in 4 vols. 8vo. His writings include a number of essays contributed to the *Edinburgh Review* from 1804 onwards, various papers in the *Phil. Trans.* (including his earliest publication "On the Arithmetic of Impossible Quantities," 1779, and an "Account of the Lithological Survey of Schiehallion" 1811) and in the *Transactions of the Royal Society of Edinburgh* ("On the Causes which affect the Accuracy of Barometrical Measurement," &c.), also the articles "Æpinus" and "Physical Astronomy," and a "Dissertation on the Progress of Mathematical and Physical Science since the Revival of Learning in Europe," in the *Encyclopædia Britannica* (Supplement to fourth, fifth, and sixth editions). His *Elements of Geometry* first appeared in 1795 and have passed through many editions; his *Outlines of Natural Philosophy* (2 vols., 1812–16) consist of the propositions and formulæ which were the basis of his class lectures. Playfair's contributions to pure mathematics were not considerable, his paper "On the Arithmetic of Impossible Quantities," that "On the Causes which affect the Accuracy of Barometrical Measurements," and his *Elements of Geometry*, all already referred to, being the most important. As a mathematician simply he was far inferior to the first two Gregorys, to Colin Maclaurin, and even to Matthew Stewart. He was, however, a man of great general ability and was conspicuous for a calm intellect. His scientific style was a model of clearness, and his *Illustrations of the Huttonian Theory of the Earth* attained great popularity through its literary merits. His lives of Matthew Stewart, Hutton, Robison, many of his reviews, and above all his "Dissertation" are of the utmost value. The English mathematicians of his day professed unlimited admiration of Newton, but few of them were found able to wield his weapons, and the majority had come simply to rest under the shadow of that great man; to Playfair belongs the credit of having been one of the first to diffuse among his countrymen a knowledge of the substantial progress which the infinitesimal calculus had been making in the hands of the Continental analysts.

PLEADING, in law, denotes in civil procedure the statement in legal form of the grounds on which a party to an action claims the decision of the court in his favour, in criminal procedure the accusation of the prosecutor or the answer of the accused. The term "pleadings" is used for the collected whole of the statements of both parties, the term "pleading" for each separate part of the pleadings. A pleading may be the statement of either party; a "plea" is (except in Scots and ecclesiastical law) confined to the defence made by an accused person. To "plead" is to frame a pleading or plea.

All systems of law agree in making it necessary to bring the grounds of a claim or defence before the court in a more or less technical form. In Roman law the action passed through three stages (see ACTION), and the manner of pleading changed with the action. In the earliest historical period, that of the *legis actiones*, the pleadings were verbal, and made in court by the parties themselves, the proceedings imitating as far as possible the natural conduct of persons who had been disputing, but who suffered their quarrel to be appeased (Maine, *Ancient Law*, ch. x.). Though pleadings were probably not couched in technical language originally, this soon became a necessity,

¹ "After Plautus died, comedy mourns, the stage is deserted, then laughter, mirth, and jest, and his numberless numbers all wept in concert."

and was regarded as so important that, as Gaius tells us, the party who made even the most trifling mistake would lose his suit. This excessive reverence for formality is a universal characteristic of archaic law. Its probable explanation is to be found in the weakness of the executive. In the second period, that of the procedure by *formula*, the issue which the *judex* decided was made up by the *prætor* in writing from the statements of the parties before him. The *formula* was a short summary of the facts in dispute in technical language, with instructions to the *judex*. The part of the *formula* which contained the plaintiff's claim was called the *intentio*. Any equitable defence in the *formula* was set up by means of an *exceptio*, which was either peremptory, denying the right of the plaintiff to recover at all, or dilatory, denying only that the action could be brought at the time or by the particular plaintiff. The plaintiff might meet the *exceptio* with a *replicatio*, the defendant on his side might set up a *duplicatio*, and the plaintiff might traverse the *duplicatio* by a *triplicatio*. The parties might proceed even further, but beyond this point the pleadings had no special names. Actions *bonæ fidei* implied every *exceptio* that could be set up; in other actions the *exceptio* must be specially pleaded. From the *formula* the *judex* derived his whole authority, and he was liable to an action for exceeding it. He could not amend the *formula*; that could only be done by the *prætor*. In the third period the *formula* did not exist, the plaintiff's claim appeared in the summons (*libellus conventionis*), and the defendant might take any defence that he pleased, all actions being placed on the footing of actions *bonæ fidei*. The issue to be tried was determined by the judge from the oral statements of the parties. In criminal procedure the indictment (*inscriptio* or *libellus accusationis*) was usually in writing, and contained a formal statement of the offence. In some cases oral accusations were allowed. The pleading of the accused seems to have been informal.

The development of the system of pleading in Roman and English law proceeded upon very similar lines. It is possible that the English system was directly based upon the Roman. Bracton (*temp.* Henry III.) uses many of the Roman technical terms. Pleading was oral as late as the reign of Henry VIII., but in the reign of Edward III. pleadings began to be drawn up in writing, perhaps at first more for the purpose of entry on the court records than of the instruction of the court (see 2 Reeves, *History of English Law*, 398). The French language was used up to 36 Edw. III. st. 1, c. 15, after which English was used for oral pleading, but Latin for enrolment. Latin was the language of written pleadings at common law until 4 Geo. II. c. 26.¹ Such terms as *declaration*, *answer*, *replication* are survivals of the oral period. It is no doubt from the circumstance of pleading having been originally oral that the word in the popular though not in the legal sense is used for the oral conduct of the case by an advocate.² The period of the Roman *formula* has its analogue in the period of the original writ in England.³ The writ was at first a formal commission from the crown to a judicial officer to do justice between the parties, the claim being made by means of a count. The issue of the writ was part of the prerogative of the crown, unlimited until the Provisions of Oxford (1258) forbade the issue of fresh writs (except writs *de cursu*) without the consent of

the council. Gradually the writ came to absorb the count and included the plaintiff's claim and sometimes the nature of his evidence. The defendant pleaded to the writ. The writ became the universal form of instituting proceedings in the king's court, irrespective of the method of trial which followed, and probably grew fixed in form about the reign of Henry II. (see Bigelow, *History of Procedure*, ch. iv.). At a later date the writ again tended to approach its earlier form and to split into two parts, the writ of summons and the declaration or plaintiff's claim. The writ of summons was addressed to the defendant, and not, as the original writ, to a judicial officer. The pleading became the act of the party, differing in this from Roman law, in which they were a judicial act. The writs became precedents for the forms of action, which, like the writs, were limited in number. The plaintiff's claim was a substantial repetition of the writ. Modern legislation, in the case of the specially indorsed writ of summons (see below), practically returns to this ancient stage of law. In the writ, as in the *formula*, the slightest failure in form was as a rule fatal. "The assigning of a writ of a particular frame and scope to each particular cause of action, the appropriating process of one kind to one action and of a different kind to another, these and the like distinctions rendered proceedings very nice and complex, and made the conduct of an action a matter of considerable difficulty" (1 Reeves, *Hist. of English Law*, 147). Fines were levied for mistakes in pleading, non-liability to which was sometimes granted by charter as a special privilege to favoured towns. In both Roman and English law fictions, equity, and legislation came to mitigate the rigour of the law. In England this result was largely attained by the framing of the action of trespass on the case under the powers of the Statute of Westminster the Second (13 Edw. I. stat. 1, c. 24), and by the extension of the action of *assumpsit* to non-feasance. To a less extent the same difficulties were found in the period of special pleading⁴ which followed the writ period, owing to the particularity with which the claim had to be set out and the narrow powers of amendment possessed by the courts. The practical questions at issue were thrown into the shade by questions of the proper way of stating them. Substantive law could only be arrived at through the medium of adjective law. Special pleading became an art of the utmost nicety, depending on numerous rules, some of them highly technical (see Coke upon Littleton, 303). Those who made it their business to frame pleadings were called special pleaders. They were not necessarily members of the bar, but might be licensed to practise under the bar. Pleaders under the bar still exist, but recent legislation has much diminished their numbers and importance. Changes were gradually introduced by a long series of statutes of which the most important have been the Statutes of Jeofails, beginning as early as 14 Edw. III., c. 6, the Statutes of Set-off, the Common Law Procedure Acts, and the Judicature Acts. The advance has always been, as in Roman law, in the direction of less formality. Up to 1875 the system of pleading varied in the different courts which now compose the High Court of Justice. In the Common Law Courts the action was commenced by a *declaration* (containing either *special* or *common counts*, or both combined), to which the defendant put in a *plea* or *pleas*. The plea was either of the general issue, *i.e.*, a bare denial (as "Never Indebted" to an action of debt), or special, setting out the facts with greater particularity. Pleas were also peremptory or dilatory, names taken from the Roman law.

¹ In Chancery the "English Bill," so called from its being in the English language, had existed long before this time,—according to Mr Spence, as early as the reign of Henry V. (*Equitable Jurisdiction*, vol. i. p. 348).

² In France *plaidier* and *plaidoyer* still bear this meaning.

³ The original writ was so called to distinguish it from the judicial writ, which was a part of the process of the court. The judicial writs still exist, *e.g.*, writs of *certiorari* or *feri facias*.

⁴ The ingenuity of the pleader chiefly showing itself in framing special as opposed to general pleas, the term special pleading grew to be used for the whole proceedings of which it was the most important part.

By the Common Law Procedure Act, 1854, equitable pleas might be pleaded. To the defendant's plea the plaintiff pleaded a *replication*; the defendant might follow with a *rejoinder*, the plaintiff with a *surrejoinder*, the defendant with a *rebutter*, the plaintiff with a *surrebutter*. Beyond that point, which was seldom reached, the pleadings had no special names. The pleadings concluded with a *joinder of issue*. A copy of the pleadings constituted the *record*. Since the Judicature Acts there has been no record, properly so called, in civil cases, though it has not been expressly abolished. Its place is supplied by copies of the pleadings delivered for the use of the judge and of the officer entering the judgment under the Rules of the Supreme Court, 1883 (Ord. xxxvi. r. 30; Ord. xli. r. 1). Either party might demur at any stage of the pleadings (see DEMURRER). In certain cases the replication of the plaintiff proceeded by way of *new assignment*; e.g., in an action of trespass to which justification was pleaded, the plaintiff might complain of acts in excess of those covered by the justification. In this case he was said to new assign, and the defendant pleaded to the new assignment. In the Court of Chancery the plaintiff's claim was contained in a *bill* (in certain matters of a public nature an *information*), to which the defendant filed an *answer* on oath or a *demurrer* or, more rarely, *pleas*, and the plaintiff a *replication*. Beyond the replication equity pleadings did not extend, the place of further pleadings being supplied by amendment. *Exceptions* (note again a Roman law term) might be taken to the bill or answer on various grounds. Equity pleadings, unlike common law pleadings, were signed by counsel.¹ In the High Court of Admiralty the pleadings were called *petition*, *answer*, *reply*, and *conclusion*. In the Court of Probate they were called *declaration*, *plea*, and *replication*, but the procedure was not the same as that in use in the Common Law Courts. In all the courts a *special case* without pleadings could by leave of the court be stated for the opinion of the court.

The Judicature Act, 1873, introduced a uniform system of pleading in the High Court of Justice. The practice is now regulated by the Rules of the Supreme Court, 1883. By Ord. xix. r. 4, "every pleading shall contain, and contain only, a statement in a summary form of the material facts on which the party pleading relies for his claim or defence, as the case may be, but not the evidence by which they are to be proved, and shall, when necessary, be divided into paragraphs, numbered consecutively. Dates, sums, and numbers shall be expressed in figures and not in words. Signature of counsel shall not be necessary; but where pleadings have been settled by counsel or a special pleader they shall be signed by him, and if not so settled they shall be signed by the solicitor or by the party if he sues or defends in person." The term "pleading" in the Judicature Acts includes a petition or summons, 36 & 37 Vict. c. 66, § 100. From 1875 to 1883 the plaintiff had in almost every case to deliver a *statement of claim*. But now no statement of claim is delivered where the action is commenced by a specially indorsed writ, or where the writ is not specially indorsed unless the defendant gives notice in writing that he requires a statement of claim to be delivered.² The defendant presents his case in a *statement of defence*, and may also *set off* or set up by way of *counter-claim* any right or claim against the plaintiff whether sounding in damages or not. A counter-claim

may be made against the plaintiff and a third party. To a statement of defence or counter-claim the plaintiff or third party delivers a *reply*. No pleading other than a joinder of issue can be pleaded after reply except by leave of the court or a judge. Both the parties and the court or a judge have large powers of amending the pleadings. Issues are in certain cases settled by the court or a judge. Demurrers are abolished, and a party is now entitled to raise by his pleading any point of law. Forms of pleadings are given in Appendices C, D, and E to the Rules of 1883. In actions for damages by collision between ships, a document called a *preliminary act* (before the Judicature Act peculiar to the Court of Admiralty) must be filed, containing details as to the time and place of collision, the speed, tide, lights, &c. The case may be tried on the preliminary act without pleadings. In all actions such ground of defence or reply as if not raised would be likely to take the opposite party by surprise, or would raise issues of fact not arising out of the preceding pleadings, must be specially pleaded. Such are compulsory pilotage, fraud, the Statute of Limitations, the Statute of Frauds. The pleadings in *replevin* and *petition of right* are governed by special rules. To courts other than the High Court of Justice the Judicature Acts do not apply. In some courts, however, such as the Chancery of the County Palatine of Lancaster and the Court of Passage of the City of Liverpool, the rules of pleading used in the High Court have been adopted with the necessary modifications. In the Mayor's Court of London the common law pleading, as it existed before the Judicature Acts, is still in use. In the ecclesiastical courts the statements of the parties are called generally *pleas*. The statement of the plaintiff in civil suits is called a *libel*, of the promoter in criminal suits *articles*. Every subsequent plea is called an *allegation*. To the responsive allegation of the defendant the promoter may plead a counter-allegation. The cause is concluded when the parties renounce any further allegation. In the Divorce Court the pleadings are named *petition*, *answer*, *replication*. In that court and in the ecclesiastical courts there exists in addition a more short and summary mode of pleading called an *act on petition*. In the county courts proceedings are commenced by a *plaint*, followed by an *ordinary* or *default summons*. No further pleadings are necessary, but the defendant cannot set up certain special defences, such as set-off or infancy, without the consent of the plaintiff, unless after notice in writing of his intention to set up the special defence.

The pleading in English criminal law has been less affected by legislation than the pleading in actions. The pleading is more formal, and oral pleading is still retained. Cases in which the crown was a party early became known as pleas of the crown (*placita coronæ*), as distinguished from common pleas (*communia placita*), or pleas between subject and subject, that is to say, ordinary civil actions. Pleas of the crown originally included all matters in which the crown was concerned, such as exchequer cases, franchises, and liberties, but gradually became confined to criminal matters, strictly to the greater crimes triable only in the king's courts. In criminal pleading the crown states the case in an *indictment* or *information*. The answer of the accused is a *plea*, which must in almost all cases be pleaded by the accused in person. The plea, according to Blackstone, is either to the jurisdiction, a demurrer, in abatement, special in bar, or the general issue. The latter is the only plea that often occurs in practice; it consists in the oral answer of "Guilty" or "Not Guilty" to the charge. A demurrer is strictly not a plea at all, but an objection on legal grounds. Pleas to the jurisdiction or in abatement do not go to the merits of the case, but allege that the court has no jurisdiction to

¹ For the pleading before 1875 see Stephen on *Pleading* for the Common Law Courts, Story on *Equity Pleading* for the Court of Chancery, and the articles BILL and DECLARATION.

² A specially indorsed writ may be used in an action for a debt or liquidated demand. The advantage of using it is that the defendant must obtain leave to defend the action by showing to the satisfaction of a judge that he has reasonable grounds of defence.

try the particular offence, or that there is a misnomer or some other technical ground for stay of proceedings. The power of amendment and the procedure by motion in arrest of judgment have rendered these pleas of little practical importance. The special pleas in bar are *autrefois convict* or *autrefois acquit* (alleging a previous conviction or acquittal for the same crime), *autrefois attain* (practically obsolete since the Felony Act, 1870, has abolished attainder for treason or felony), and pardon (see PARDON). There are also special pleas in indictments for libel under the provisions of Lord Campbell's Act, 6 & 7 Vict. c. 96 (see LIBEL), and to indictments for non-repair of highways and bridges, where the accused may plead that the liability to repair falls upon another person. These special pleas are usually, and in some cases must be, in writing. Where there is a special plea in writing, the crown puts in a *replication* in writing. (For the history of criminal pleading see Stephen, *History of the Criminal Law*, vol. i. ch. ix.)

In Scotland an action in the Court of Session begins by a *summons* on the part of the pursuer to which is annexed a *condescendence*, containing the allegations in fact on which the action is founded. The *pleas in law*, or statement of the legal rule or rules relied upon (introduced by 6 Geo. IV. c. 120, § 9), are subjoined to the condescendence. The term *libel* is also used (as in Roman law) as a general term to express the claim of the pursuer or the accusation of the prosecutor. The statement of the defender, including his pleas in law, is called his *defences*. They are either dilatory or peremptory. There is no formal joinder of issue, as in England, but the same end is attained by adjustment of the pleadings and the closing of the record. Large powers of amendment and revisal are given by the Court of Session Act, 1868. In the Sheriff Court pleadings are very similar to those in the Court of Session. They are commenced by a *petition*, which includes a condescendence and a note of the pursuer's pleas in law. The defender may upon notice lodge defences. The procedure is now governed by 39 & 40 Vict. c. 70. The term "pleas of the crown" is confined in Scotland to four offences—murder, rape, robbery, and fire-raising. A prosecution is commenced either by *indictment* or *criminal letters*, the former being the privilege of the lord advocate. In the Supreme Court the indictment or criminal letters run in the name of the lord advocate; in the Sheriff Court the criminal letters (indictments not being used in that court) run in the name of the judge. The Scotch indictment differs from the English, and is in the form of a syllogism, the major proposition stating the nature of the crime, the minor the actual offence committed and that it constitutes the crime named in the major, the conclusion that on conviction of the panel he ought to suffer punishment. The panel usually pleads "Guilty" or "Not Guilty" as in England, but he may plead in bar want of jurisdiction or *res judicata*, or make special defences (such as *alibi* or insanity), which must be lodged with the clerk of the court in writing signed by him or his counsel. The special defence is read to the jury immediately after they have been sworn. (See Macdonald, *Criminal Law of Scotland*.)

In the United States two systems of pleading in civil procedure exist side by side. Up to 1848 the pleading did not materially differ from that in use in England at the same date. But in 1848 the New York legislature made a radical change in the system, and the example of New York has been followed by more than twenty States. The New York Civil Code of 1848 established a uniform procedure called the civil action, applicable indifferently to common law and equity. The pleadings are called *complaint*, *answer* (which includes *counterclaim*), and *reply*. The *demurrer* also is still used. In some States which follow the new procedure the complaint bears the name of *petition*. In the inferior courts, such as courts of justices of the peace, the pleadings are more simple, and in many cases oral. In States which do not adopt the amended procedure, the pleading is much the same as it was in the days of Blackstone, and the old double jurisdiction of common law and equity still remains. Criminal pleading differs little from that in use in England. (See Bishop, *Law of Criminal Procedure*.)

(J. Wt.)

PLEBEIANS. See NOBILITY and ROME.

PLEDGE, or PAWN, in law, is "a bailment of personal property as a security for some debt on engagement." (Story on *Bailments*, § 286). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law, from which most of the modern law on the subject is derived. It differs from hypothec and from the more usual kind of mortgage in

that the pledge is in the possession of the pledgee; it also differs from mortgage in being confined to personal property. A mortgage of personal property in most cases takes the name and form of a bill of sale (see BILL, the giving of bills of sale being now regulated by the Bills of Sale Acts, 1878 and 1882). The chief difference between Roman and English law is that certain things, *e.g.*, wearing apparel, furniture, and instruments of tillage, could not be pledged in Roman law, while there is no such restriction in English law. In the case of a pledge, a special property passes to the pledgee, sufficient to enable him to maintain an action against a wrongdoer, but the general property, that is the property subject to the pledge, remains in the pledgor. As the pledge is for the benefit of both parties, the pledgee is bound to exercise only ordinary care over the pledge. The pledgee has the right of selling the pledge if the pledgor make default in payment at the stipulated time. No right is acquired by the wrongful sale of a pledge except in the case of property passing by delivery, such as money or negotiable securities. In the case of a wrongful sale by a pledgee, the pledgor cannot recover the value of the pledge without a tender of the amount due. For pledges by factors see FACTOR. A pledge by a banker, merchant, broker, attorney, or other agent, in violation of good faith, and contrary to the purpose for which the property pledged was intrusted to him, or a pledge of property with which he was intrusted for safe custody, renders the offender guilty of a misdemeanor, punishable with a maximum term of seven years' penal servitude, 24 & 25 Vict. c. 96, §§ 75, 76. Pledges with pawnbrokers are regulated by the Pawnbrokers' Act, 1872, 35 & 36 Vict. c. 93 (which applies to Great Britain). By the provisions of the Act (which does not affect loans above £10), a pledge is redeemable within one year and seven days of grace added to the year. Pledges pawned for 10s. or under not redeemed in time become the property of the pawnbroker, pledges above 10s. are redeemable until sale. The sale must be by public auction. The pawnbroker is entitled to charge as interest one halfpenny per month on every two shillings lent where the loan is under 40s., on every two shillings and sixpence where the loan is above 40s. Special contracts may be made where the loan is above 40s. Unlawful pawning of goods not the property of the pawner, and taking in pawn any article from a person apparently under the age of sixteen or intoxicated, or any linen or apparel or unfinished goods or materials intrusted to wash, make up, &c., are (*inter alia*) made offences punishable by summary conviction. An annual licence, costing £7, 10s., must be taken out for every pawnbroker's shop.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and Louisiana a pledge cannot be sold unless with judicial authority. In some of the States the common law as it existed apart from the Factors' Acts is still followed; in others the factor has more or less restricted power to give a title by pledge. In some States pawnbroking is regulated by the local authorities, and not, as in most, by the general law of the State.

PLESIOSAURIANS. The remarkable extinct marine reptiles included in the group of the *Plesiosauria* (or *Sauropterygia*, as they are sometimes called) existed during the whole of the Mesozoic period, that is, from Triassic into Cretaceous times, when they appear to have died out. The best known of these reptiles, and that which gives its name to the group is the *Plesiosaurus*, a genus established by Conybeare in 1821, and including numerous species, some of which may have attained a length of as much as 20 feet. The nearly allied *Elasmosaurus* of North America, however, reached a much greater size, its remains indicating an animal about 45 feet in length. Several almost perfect skeletons of *Plesiosaurus* having at

different times been found, the general proportions of the body are well known. Although the different species vary in regard to proportions, the small size of the head and extreme length of the neck are always striking points in the skeleton of a *Plesiosaurus*, while the tail is proportionately short. The limbs, both fore and hind, are well developed and modified for swimming, the forms of the various bones making it clear that the digits of each limb were not separate, but enclosed in one covering of integument, as in the flippers of a whale or a turtle. The exterior of the body, there is every reason to believe, was smooth as it is in *Cetacea*, and not provided with either

bony or horny scutes or scales as in the living crocodiles and turtles. The internal skeleton therefore is the only part available for study.

The skull of *Plesiosaurus* has a tapering and depressed snout, and in consequence of the large size of the premaxillary bones the nasal apertures are placed far back, just in front of the orbit, as in birds. There is a distinct parietal foramen, as in lizards. The orbit is completely surrounded by bone, and there are supra- and infra-temporal fossæ. The single occipital condyle is formed almost entirely by the basi-occipital bone. The basi-sphenoid is well developed, and is produced into a long

FIG. 1.—*Plesiosaurus* (after Owen).

rostrum. On the base of the skull four fossæ are to be seen; the front pair of these are bounded behind by the palatine bones, and are regarded as the true posterior nares. The teeth are slender, sharp, curved, and striated; they have single fangs, and are placed loosely in separate alveolar sockets.

The spinal column is composed of a large number of vertebrae, some species having ninety or more in the entire series. The centrum of each vertebra has the fore and hind surfaces slightly concave; the neural arch is connected with the centrum by a suture, which seems never to have been entirely obliterated. The cervical vertebrae vary in number from twenty-four to upwards of forty in different species. Each is provided with a pair of ribs, closely resembling those found in the cervical region in the crocodile, but with a single articular head only. Towards the hinder part of the neck the ribs become more elongated, and take on the form of dorsal ribs; but, as none of the ribs join the sternum, the usual means of distinguishing the dorsal and cervical regions is wanting. There may be from twenty to thirty dorsal vertebrae. True sternal ribs have never been detected; but abdominal

front and outside of which is a peculiarly shaped scapula with a plate extending dorsally from the glenoid cavity, and a second process directed inwards and downwards. The latter process is now regarded as the precoracoid by Mr J. W. Hulke, who also considers the plate of bone—originally of two pieces—found in the middle and in front of the coracoids to be the homologue of the omosternum of *Batrachia*. If this

interpretation be correct, *Plesiosaurus* has neither clavicles nor interclavicles. In the fore limb all the characteristic bones are present. The humerus is an elongated bone with the anterior border nearly straight and the hinder border concave; it is rounded at the upper end, and flattened below, where it is articulated to two much shorter bones, the radius and ulna. Next to these is a row of three carpal bones—the radiale (scaphoid), the ulnare (cuneiform), and the intermedium (lunar); a second row of four bones succeeds these, three of which are carpals, but the outer one may be a metacarpal; next comes a row of five metacarpals. The digits are five in number, and with the exception of the first are made up of numerous separate ossicles, or phalanges.

The pelvic arch (fig. 3) is large, and ventrally consists of a pair of flattened more or less quadrate pubes, and a pair of somewhat triangular ischia. The iliac bones are elongated, narrower where they form part of the acetabular articulation and becoming broader above where they join the sacral ribs. The hind limb very closely resembles the fore limb. The front and back margins of the femur are straighter than they are in the humerus; but the other parts almost exactly repeat the corresponding bones of the fore limb.

With regard to the probable habits of the *Plesiosaurus* we are not without some indications. The paddle-like form of the limbs leaves no doubt as to its aquatic mode of life, and judging from the fossils with which it is usually associated it must have been an inhabitant of the sea; it is highly probable, however, that some species at least ascended rivers, for remains of *Plesiosauria* are found in the Wealden freshwater deposits. The comparatively small tail and large paddles render it probable that the limbs were the chief means of propulsion. The long neck would tend to impede its progress through the water, and it would be better adapted, therefore, for swimming on or near the surface. It is unlikely that the *Plesiosaurus* could move as rapidly through the water as the *Ichthyosaurus*; but this slower movement would be compensated for by the rapidity with which its long and flexible neck could be darted at its prey. Seeing that the marine turtles and seals of the present day make their way on shore, it is quite possible that the *Plesiosaurus* may also have occasionally visited the

bones, or ribs, are well developed. The sacrum consists of two vertebrae, with stout broad ribs for attachment to the iliac bones. The caudal vertebrae, between thirty and forty in number, have distinct chevron bones, which are attached between the successive vertebrae. The pectoral arch (fig. 2) consists of a large coracoid on each side, in

land. The sharp and slender teeth would be admirably adapted for catching and holding a slippery prey, and there is no doubt that fishes formed in part, if not altogether, its natural food. Indeed the scales and teeth of fishes have been found, in one case at least, just below the vertebrae, in the region which must have been occupied by the creature's stomach.

It is of interest to note the differences which exist between the *Plesiosaurus* and the *Ichthyosaurus* (*q.v.*), the latter being the type of another group, the *Ichthyosauria*, which is by some palaeontologists included with the *Plesiosauria* in a larger group called *Enaliosauria*. In outward form the *Ichthyosaurus* must have resembled some of the recent *Cetacea*, inasmuch as the head is proportionately large, and without any appearance of a neck joins directly on to the trunk. The hind limbs are smaller than the front ones, and the bones of both limbs are much more shortened and flattened than in *Plesiosaurus*; in addition to this there are supernumerary rows of bones, besides the five typical digital series. The pectoral arch differs in having distinct clavicles and interclavicles. The vertebrae are short from back to front, deeply biconcave, and their neural arches never have a bony connexion with the centra. There is no sacrum. The teeth are placed in a groove, and not in separate sockets. The eye-ball was protected by a series of bony sclerotic plates, which are not found in *Plesiosaurus*.

The group *Plesiosauria* includes several other genera besides the *Plesiosaurus*; but most of these are only represented by such imperfect specimens that the distinctions between them, as at present known, are far from satisfactory. The characters which have been relied upon for their separation are to be found chiefly in the structure of the pectoral arch, limbs, and vertebrae. *Plesiosaurus* is only certainly known to have existed from the time of the Lower Lias to the Chalk; and it is especially characteristic of the Lias. More than fifty species, sometimes placed in several subgenera, have been described from different localities in Britain, some of which are represented by remarkably perfect specimens, and others by fragments only. This genus has a wide geographical distribution, species having been named from Secondary strata, on the continent of Europe, in India, Australia, South America, and North America. The closely allied and gigantic form *Phiosaurus* is chiefly characteristic of the English Oolites.

In European Triassic beds, *Plesiosauria* are represented by such genera as *Nothosaurus*, *Simosaurus*, and *Pistosaurus*, in all of which the neural arches seem to have been less closely united to the vertebral centra than in *Plesiosaurus*. *Neusticosaurus* is another Triassic form, remarkable, not only on account of its small size, being less than 12 inches in length, but also because its limbs seem to show a transitional condition; for, while the structure of the hind limb resembles that of a land reptile, the fore limb seems to have had more the structure of a paddle.

A number of forms closely related to the *Plesiosaurus* have been described from rocks of Cretaceous age in North America under the following generic names — *Cimoliasaurus*, *Elasmosaurus*, *Oligosimus*, *Piratosaurus*, and *Polycotylus*. Of these the *Elasmosaurus* is better known than any of the others. It was an extremely elongated form, as may be gathered from the fact that the snake-like neck alone consisted of more than sixty vertebrae, — the entire body, as we have noticed above, being more than 45 feet in length.

PLETHO. See GEMISTUS.

PLEURISY, or PLEURITIS, inflammation of the pleura or serous membrane investing the lungs and lining the interior of the thoracic cavity. It is a common form of chest complaint, and may be either acute or chronic, more frequently the former.

The morbid changes which the pleura undergoes when inflamed are similar to those which take place in other serous membranes, such as the peritoneum (see PERITONITIS), and consist of three chief conditions or stages of progress. (1) Inflammatory congestion and infiltration of the pleura, which may spread to the tissues of the lung on the one hand, and to those of the chest wall on the other. (2) Exudation of lymph on the pleural surfaces. This lymph is of variable consistence, sometimes composed of thin and easily separated pellicles, or of extensive thick masses or strata, or again showing itself in the form of a tough membrane. It is of greyish-yellow colour, and

microscopically consists mainly of coagulated fibrine along with epithelial cells and red and white blood corpuscles. Its presence causes roughening of the two pleural surfaces, which, slightly separated in health, may now be brought into contact by bands of lymph extending between them. These bands may break up or may become organized by the development of new blood-vessels, and adhering permanently may obliterate throughout a greater or less space the pleural sac, and interfere to some extent with the free play of the lungs. (3) Effusion of fluid into the pleural cavity. This fluid may vary in its characters. Most commonly it is clear or slightly turbid, of yellowish-green colour, sero-fibrinous, and containing flocculi of lymph. In bad constitutions or in cases where the pleurisy complicates some severe form of disease, *e.g.*, the acute infectious maladies, it is deeply-coloured, bile-stained, sero-purulent, purulent, or bloody, occasionally containing bubbles of air from decomposition. The amount may vary from an almost inappreciable quantity to a gallon or more. When large in quantity it may fill to distension the pleural sac, bulge out the thoracic wall externally, and compress more or less completely the lung, which may in such cases have all its air displaced and be reduced to a mere fraction of its natural bulk lying squeezed up upon its own root. Other organs, such as the heart and liver, may in consequence of the presence of the fluid be shifted away from their normal position. In favourable cases the fluid is absorbed more or less completely and the pleural surfaces again may unite by adhesions; or, all traces of inflammatory products having disappeared, the pleura may be restored to its normal condition. When the fluid is not speedily absorbed it may remain long in the cavity and compress the lung to such a degree as to render it incapable of re-expansion as the effusion passes slowly away. The consequence is that the chest wall falls in, the ribs become approximated, the shoulder is lowered, the spine becomes curved and internal organs permanently displaced, while the affected side scarcely moves in respiration. Sometimes the unabsorbed fluid becomes purulent, and an *empyema* is the result. In such a case the matter seeks vent in some direction, and it may point as an abscess upon the chest or abdominal wall, or on the other hand burst into the lung and be discharged by the mouth. It must be observed that many cases of pleurisy do not reach the stage of effusion, the inflammation terminating with the exudation of lymph. To this form the term *dry pleurisy* is applied. Further pleurisy may be limited to a very small area, or, on the contrary, may affect throughout a greater or less extent the pleural surfaces of both lungs.

Pleurisy frequently arises from exposure to cold; hence it is more common in the colder weather; but besides this various other causes are connected with its occurrence. Thus it is often associated with other forms of disease within the chest, more particularly pneumonia, bronchitis, and phthisis, and also occasionally accompanies pericarditis. Again it is apt to occur as a secondary disease in certain morbid constitutional states, *e.g.*, the infectious fevers, rheumatism, gout, Bright's disease, diabetes, &c. Further, wounds or injuries of the thoracic walls are apt to set up pleurisy, and the rupture of a phthisical cavity in the lungs causing the escape of air and matter into the pleura has usually a similar effect.

The symptoms of pleurisy vary, being generally well-marked, but sometimes obscure. In the case of dry pleurisy, which is on the whole the milder form, the chief symptom is a sharp pain in the side, felt especially in breathing. Fever may or may not be present. There is slight dry cough; the breathing is quicker than natural, and is shallow and of catching character. If much pain is present the body leans somewhat to the affected side, to

relax the tension on the intercostal muscles and their covering, which are even tender to touch. On listening to the chest by the stethoscope the physician recognizes sooner or later "friction," a superficial rough rubbing sound, occurring only with the respiratory acts and ceasing when the breath is held. It is due to the coming together during respiration of the two pleural surfaces which are roughened by the exuded lymph. The patient may himself be aware of this rubbing sensation, and its vibration or fremitus may be felt by the hand laid upon the thoracic wall during breathing. This form of pleurisy may be limited or may extend over the greater part of one or both sides. It is a not unfrequent complication of phthisis in all its stages. In general it disappears in a short time, and complete recovery takes place; or on the other hand extensive adhesions may form between the costal and pulmonary surfaces of the pleura, preventing uniform expansion of the lung in respiration, and leading to emphysema. Although not of itself attended with danger, dry pleurisy is sometimes preliminary to more serious lung disease, and is always therefore to be regarded while it lasts with some degree of anxiety.

Pleurisy with effusion is usually more severe than dry pleurisy, and, although it may in some cases develop insidiously, it is in general ushered in sharply by rigors and fever, like other acute inflammatory diseases. Pain is felt in the side or breast, of a severe cutting character, referred usually to the neighbourhood of the nipple, but it may be also at some distance from the affected part, such as through the middle of the body or in the abdominal or iliac regions. This transference of the pain occasionally misleads the medical examiner. The pain is greatest at the outset, and tends to abate as the effusion takes place. A dry cough is almost always present, which is particularly distressing owing to the increased pain the effort excites. The breathing is painful and difficult, tending to become shorter and shallower as the disease advances and the lung on the affected side becomes compressed. The patient at first lies most easily on the sound side, but as the effusion increases he finds his most comfortable position on his back or on the affected side. When there is very copious effusion and, as is apt to happen, great congestion of the other lung, or disease affecting it, the patient's breathing may be so embarrassed that he cannot lie down.

On physical examination of the chest the following are among the chief points observed. (1) On inspection there is more or less bulging of the side affected, obliteration of the intercostal spaces, and sometimes elevation of the shoulder. (2) On palpation with the hand applied to the side there is diminished expansion of one-half of the thorax, and the normal vocal fremitus is abolished. Should the effusion be on the right side and copious, the liver may be felt to have been pushed downwards, and the heart somewhat displaced to the left; while if the effusion be on the left side the heart is displaced to the right. (3) On percussion there is absolute dullness over the seat of the effusion. If the fluid does not fill the pleural sac the floating lung may yield a hyper-resonant note. (4) On auscultation the natural breath sound is inaudible over the effusion. Should the latter be only partial the breathing is clear and somewhat harsh, with or without friction, and the voice sound is ægophonic. Posteriorly there may be heard tubular breathing with ægophony. These various physical signs render it impossible to mistake the disease for other maladies the symptoms of which may bear a resemblance to it, such as pleurodynia.

The absorption or removal of the fluid is marked by the disappearance or diminution of the above-mentioned physical signs, except that of percussion dullness, which

may last a long time, and is probably due in part to the thickened pleura. Friction may again be heard as the fluid passes away and the two pleural surfaces come together. The displaced organs are restored to their position, and the compressed lung re-expanded. Frequently this expansion is only partial, and consequently, as already indicated, the chest falls in, the respiration on one side is imperfectly performed, and the patient remains permanently short in breathing to a greater or less degree.

In most instances the termination is favourable, the acute symptoms subsiding and the fluid (if not drawn off) gradually or rapidly becoming absorbed, sometimes after re-accumulation. On the other hand it may remain long without undergoing much change, and thus a condition of *chronic pleurisy* becomes established. Such cases are to be viewed with suspicion, particularly in those who are predisposed to phthisis, of which it is sometimes the precursor.

Pleurisy may exist in a latent form, the patient going about for weeks with a large accumulation of fluid in his thorax, the ordinary acute symptoms never having been present in any marked degree. Cases of this sort are often protracted, and their results unsatisfactory as regards complete recovery.

The chief dangers in pleurisy are the occurrence of a large and rapid effusion, particularly if both sides be affected, causing much embarrassment to the breathing and tendency to collapse; the formation of an empyæma (often marked by recurring rigors and hectic symptoms); severe collateral congestion of the other lung; imperfect recovery; and the supervention of phthisis. Further the consequences are apt to be more serious where pleurisy exists as a complication of some pre-existing disease.

The treatment of pleurisy need only be alluded to in general terms. It will necessarily depend as regards details upon the form and severity of the attack. One of the first symptoms calling for treatment is the pain. Opiates in the form of morphia or Dover's powder are useful along with the application to the chest of hot poultices or fomentations sprinkled with turpentine. In severe cases much relief to the pain and difficulty of breathing may be afforded by the application of a few leeches to the side. Cases of simple dry pleurisy usually soon yield to such treatment, aided if need be by the application of a fly-blister or of iodine to the chest. The fixing as far as possible of the one side of the thorax by means of cross straps of adhesive plaster according to the plan recommended by Dr Roberts seems of use in many instances. In the case of pleurisy with effusion, in addition to these measures, including blistering, the internal use of saline cathartics and diuretics appears to be often of service in diminishing the amount of the fluid in the pleural cavity, as are also powerful diaphoretics such as pilocarpin. When these measures fail to reduce the effusion the question of the artificial removal of the fluid comes to be considered. The operation (thoracentesis) was practised by the ancient physicians, but was revived in modern times by Trousseau in France and Bowditch in America, by the latter of whom an excellent instrument was devised for emptying the chest, which, however, has been displaced in practice by the still more convenient aspirator. The propriety of this proceeding in pleurisy with effusion has been much discussed, but there now appears to be a general consent that in cases of extensive accumulation, when other means such as those briefly referred to fail to reduce or remove the fluid in a short time, the only hope of preventing such compression of the lung as will impair its function lies in the performance of thoracentesis. All the more will the operation be justifiable if the accumulated fluid is interfering with the function of other organs, such as the heart, or is attended with marked embarrassment of the breathing. The chest is punctured in the lateral or posterior regions, and in most cases the greater portion or all of the fluid may be safely drawn off. In general the operation is unattended with danger, although not entirely exempt from such risks as sudden syncope, and therefore not to be undertaken without due vigilance as well as a careful consideration of the individual case and its associations. In many instances not only is the removal of distressing symptoms speedy and complete, but the lung is relieved from pressure in time to enable it to resume its normal function. When there is any evidence that the fluid is purulent the operation should be performed early. In such cases it is sometimes necessary to establish for a time a drainage of the pleural cavity by surgical measures.

The convalescence from pleurisy requires careful tending, and the state of the chest should be inquired into from time to time, in view of the risks of more serious forms of lung disease supervening. (J. O. A.)

PLEURO-PNEUMONIA. See MURRAIN, vol. xvii. p. 60.

PLEVNA, or PLEVEN, the chief town of one of the provinces in the principality of Bulgaria, lies in the midst of a series of hills (whose crests rise above it for 200 to 600 feet) and about 6000 yards to the east of the river Vid (a tributary of the Danube), into which the streamlets by which it is traversed discharge. Its position at the meeting place of roads from Widdin, Sofia, Shipka, Biela, Zimnitsa, and Nikopoli gives it a certain military importance, and in the Russian campaign of 1877 it became one of the great centres of operation. The Russians, who had been defeated in two minor attacks on the 20th and 30th of July, were again repulsed with a loss of 18,000 men in an assault (September 7-13) in which they employed 75,000 infantry and 60,000 cavalry. They formally invested the town on October 24th and obliged Osman Pasha to surrender on December 10th. In 142 days the assailants had lost 40,000 men and the defenders 30,000. Plevna, which contains two old Christian churches as well as a number of mosques, had 11,129 inhabitants in 1881, the province at the same date containing 100,870.

See F. V. Greene, *The Russian Army and its Campaigns in Turkey in 1877-78*, London, 1879.

PLEYEL, IGNAZ JOSEPH (1757-1831), though now almost forgotten, was once one of the most popular composers in Europe. He was born at Ruppersthal, near Vienna, June 1, 1757, studied the pianoforte under Van Hal (known in England as Vanhall), and learned composition from Haydn, who became his dearest friend. He was appointed maître de chapelle at Strasburg in 1783; and in 1791 he was invited to London, where, though Haydn was also there, he achieved an immense success. On his return to Strasburg he narrowly escaped the guillotine; but, after proving that he was not an aristocrat, he was permitted to remain until 1795, when he migrated to Paris. Here he opened a large music shop, published the first complete edition of Haydn's quartets, and founded, in 1807, the pianoforte manufactory which still bears his name. He died at Paris, November 14, 1831.

Pleyel's compositions are very numerous, but it is only in the earlier ones that the fire of true genius is discernible. His daughter-in-law, Maria Pleyel, —née Moke (1811-1875), and wife of his eldest son, Camille, —was one of the most accomplished pianistes of the age.

PLINY, THE NATURALIST (23-79 A.D.). Caius Plinius Secundus, commonly distinguished as the elder Pliny, the author of the *Natural History*, is believed to have been born (23 A.D.) at Novum Comum (Como). In the first sentence of his preface he calls Catullus, born at Verona, "conterraneum meum," meaning, perhaps, a native of Gallia Cisalpina, though it may be that Verona was the actual birthplace of both.¹ At Comum, however, was the family estate which the younger Pliny inherited from his uncle. Like his nephew, the elder Pliny had seen military service, having joined the campaign in Germany under L. Pomponius Secundus;² like him also, he had been a pleader in the law-courts, and a diligent student of Greek and Roman literature. Much of his literary work was done, he tells us himself, in the hours stolen from sleep. Of his many works the *Naturalis Historia* in thirty-seven books has alone been preserved, and in a nearly complete state. This voluminous treatise professes to be an encyclopædia of Roman knowledge, mainly based on the researches and speculations of the Greeks. What A. von Humboldt

accomplished in our own times, in his great work *Cosmos*, Pliny had essayed to carry out on similar principles,—but, of course, without the scientific knowledge, and also without the comprehensive view of the universe which is the inheritance of the present age. Pliny, we must admit, was an industrious compiler, but he was not, like Aristotle, a man of original research.³

In his first book, which contains a summary of the whole work, he names the authors, both Greek and Latin, from which the matter of each book was derived.⁴ The list indeed is a surprising one, and of comparatively few have we any remains. Among Roman authors he most frequently cites Cato the censor, M. Varro, Celsus, Cornelius Nepos, Pomponius Mela, Columella; among the Greeks, Aristotle, Theophrastus, Democritus, more than one Apollodorus, Apollonius of Pergamum, and Hippocrates. The Latin writers he calls simply "auctores;" the Greeks, of whom the list is considerably longer, are "externi."

The preface, written in a rather inflated and by no means clear style, very inferior to the Latinity of the younger Pliny, is a dedication of the work in a strain of extravagant adulation to Titus, who was then, as Cæsar, joint emperor with his father Vespasian. Pliny apologizes for dedicating to such a man a work of such commonplace and hackneyed subject-matter, but he pleads the novelty of the undertaking, and boasts of being the first who had attempted so comprehensive a theme.

The work itself commences with a pantheistic definition of the universe, *Mundus*, i.e., world and sky, and the sun and stars in space. This, he says, is reasonably regarded as a divinity—eternal, boundless, uncreated, and indestructible. Nature, he adds, and Nature's work are one, and to suppose there is more than one universe is to believe there can be more than one Nature,—which he calls "furor." His theology is "agnostic," or Epicurean; if there is any God, he says, it is vain to inquire His form and shape; He is entirely a Being of feeling and sentiment and intelligence, not of tangible existence. He believes in the "religion of humanity," according to a rather recent definition of the idea. God is what Nature is; God cannot do what Nature cannot do; He cannot kill Himself, nor make mortals immortal, nor raise the dead to life, nor cause one who has lived never to have lived at all, or make twice ten anything else than twenty. The last sentence of his work is remarkable, and is characteristic of a pagan piety which takes Nature alone for its God:—"Salve, parens rerum omnium Natura, teque nobis Quiritium solis celebratum esse numeris omnibus tuis fave" (xxxvii. 205).

But, although he regarded nature as one whole, of the great doctrine of the unity of nature and the tendency of all its operations to one definite end Pliny had no correct idea. He had a great store of ill-digested knowledge, not only imperfect in itself, but put together on no consistent plan. His style too is forced and somewhat pedantic, so that to read through and understand even a single book is by no means a light task.

To give an outline sketch of the *Natural History*, it may be said that book ii. treats of earth, stars, meteorics, and terrestrial phenomena, such as earthquakes, elevation of islands, &c. Books iii. to vi. inclusive are devoted to a geographical account of the known

³ He claims for himself "ingenium perquam mediocre," *Præf.* § 12. His nephew (iii. 5, § 8) calls it "acre ingenium," which may mean active and energetic.

⁴ Hence he reckons the number of books at 36, the subject beginning with Book ii. The matter of these, he says, comprising 20,000 points worthy of attention, he has collected from the perusal of about 2000 books, and from 100 Roman authors of special note (ex exquisitis auctoribus centum), *Præf.* § 17. The first book the author regards as an appendix to the dedicatory letter or preface, "Quia occupationibus tuis publico bono parcendum erat, quid singulis contineretur libris huic epistolæ subjunxi," *Præf.* § 33.

¹ But, as has been shrewdly remarked by Mr Long, "this somewhat barbarous word is much better adapted to intimate that Catullus was a fellow-countryman of Pliny than that he was a fellow-townsmen."

² "De Vita Pomponi Secundi duo (libri)" are enumerated among his uncle's works by the younger Pliny, *Ep.* iii. 5, § 3, who adds, "a quo singulariter amatus hoc memorie amici quasi debitum munus exsolvit."

world, in giving which the author makes no mention of Strabo. Book vii. contains a physical treatise on man, his form, the laws of his birth, age, mental qualities, &c. Book viii. treats of the larger beasts, as elephants, lions, tigers, camels, descending to snakes, crocodiles, and the smaller and domesticated animals. Book ix. includes marine animals of all kinds, fishes, shells, crustaceans, sponges, &c. Book x. is on birds, xi. on insects,—the latter half being devoted to an anatomical description of animals generally. Book xii. is on trees; xiii. on their products, fruit, gums, perfumes, &c.; xiv. on the grape and the making of wine; xv. on the olive, fig, apple, and other luscious fruits; xvi. on forest trees, canes, and reeds, kinds of timber, and different ages of trees. Book xvii. treats chiefly of the culture of trees, their diseases, and the arts of pruning, manuring, training, &c. Book xviii. is on farming and cereal crops; xix. on other kinds of produce, including horticulture; xx. on the medicinal properties of plants; xxi. on flowers, bees, honey, and on botanical distinctions as to leaves, thorns, and times of flowering. Book xxii. treats of all kinds of herbs used in medicine and in cookery; xxiii. the medicinal properties of cultivated trees; xxiv. the same of forest trees, and their useful products generally. (These two books are chiefly derived from Greek authorities, and include the names and properties of a vast number of species.) Books xxv. to xxvii. inclusive treat of the properties of plants, and these books also are chiefly from Greek sources,—Cornelius Celsus being the principal Roman authority. Books xxviii. to xxx. discuss the medicinal properties residing in animals; xxxi. and xxxii. those in fishes. These books are full of the most extraordinary and nonsensical superstitions, including discussions on magic in book xxx. Book xxxiii. is on the nature and use of the precious metals; xxxiv. on the different kinds of bronze, on lead, iron, and the oxides generally. Book xxxv. is on the origin and practice of painting; xxxvi. on the different kinds of stone and marble, including lime, sand, and gypsum; xxxvii. on precious stones.

It will be observed that, though there is no scientific classification in this long work, a kind of sequence, not altogether unphilosophical, is observed. The amount of matter and the number of subjects treated of in each book are always recorded at the end of the epitome (book i.), just before the list of authors, in the formula, "Summa: res et historiae et observationes MDCVI." &c.; but in the medical books, in place of *res*, "subjects," *medicinæ*, "prescriptions," is used. By *historiæ* he means "inquiries," or "the results of inquiries," as distinguished from *observationes*, "remarks."

With all its faults, inevitable to the infant state of science, Pliny's work is an astounding monument of industry. It is believed to have been published about two years before his death. He wrote, besides several other treatises,¹ a history of the wars from the first in Germany,² in twenty books, and a continuation of the history of Aufidius Bassus down to his own times, in thirty-one books—all now lost.

He is said to have been a great student, an early riser, abstemious and temperate in his meals.³ In his later days he appears to have grown somewhat unwieldy and asthmatic, for Pliny the younger, in describing his uncle's death by suffocation from the fumes in the eruption of Vesuvius, 79 A.D., says that his breathing "propter amplitudinem corporis gravior et sonantior erat."⁴ Pliny's intimate friendship with Vespasian may be inferred from his custom of attending the morning levée; he seems to have first known him in the German wars in the time of Claudius.

Besides his published works, the elder Pliny left, as his nephew tells us, one hundred and sixty note-books of extracts (electorum commentarios clx.), written in a very small hand on both sides of the page. So valuable were these volumes considered that Pliny assured his nephew he could have sold them in Spain for £3500, even before the full number had been made up. He acted as procu-

rator in Spain in 71, and was recalled to Rome by the death of his brother-in-law Caius Cæcilius, who by will appointed him guardian of the younger Pliny. At the time of his death, the elder Pliny had the command of the Roman fleet at Misenum. He fell a victim to his imprudent curiosity in advancing within the range of the thickly-falling ashes during the eruption of Vesuvius in 79 A.D.

Pliny's influence on the nomenclature and the popular ideas about common objects long continued to be very extensive, and survived till the dawn of the age of more exact science. The knowledge he gives us of the writings and opinions of so large a number of lost authors opens a view of the whole cycle of the science of the period.

The best editions of the *Natural History* are those by Julius Sillig (Leipsic, 1831-36, in 5 vols. 12mo), and by Louis Janus (Teubner, Leipsic, 1854-59, in 6 vols.), which is virtually a revised reprint of it, the whole of the last volume being occupied with copious and accurate indices of authors and subjects. These may be called critical editions; two French editions with scientific commentaries had preceded,—by Hardouin (1685 and 1723), and by Panckoucke (1829-33), in twenty volumes with a French translation. (F. A. P.)

PLINY THE YOUNGER (61-c. 115 A.D.). Caius Cæcilius Secundus, commonly called Pliny the Younger, was the nephew and heir of the elder Pliny, the naturalist. He was born 61 A.D. at Comum (Como) on the southern shore of Lake Larius in northern Italy, near to which, on the east side, stood the spacious and beautiful family villa.⁵ He took the name of Cæcilius from his father, who had married Plinia, the elder Pliny's sister. At ten years of age he was left to the care of Virginus Rufus, a distinguished man and thrice consul.⁶

Pliny was a man of refined taste, highly accomplished, devoted to literature, kind and indulgent to his freedmen and his slaves, gentle and considerate in all his family relations, just in his dealings, munificent in the use of his wealth, humane and forgiving to all who had offended him.⁷ By profession an advocate, and a pupil of the famous Quintilian (ii. 14), he was a frequent and very popular pleader at the courts of the centumviri held in the Julian basilica, as well as occasionally in the senate and in public prosecutions (vi. 29).

His fame in centumviral trials, which were chiefly concerned with will cases, is attested by Martial (x. 19, 17), whose epigram he quotes in lamenting the poet's death (iii. 21). But, though himself somewhat ambitious of praise as a pleader (for he seems to have regarded Cicero as his model in everything), he sternly reproved the arts of bribery and flattery which were commonly adopted by patrons to secure the applause of their clients. "For half-a-crown a head," he complains, "you may fill the benches with any number of shouters and bawlers of your praises." Fond as he was of eloquence, he seems to have given up legal practice from some feeling of disgust at these abuses, and to have devoted himself to the duties of the state-offices. He was appointed augur and præfect of the treasury in the temple of Saturn, and rose in due course through the offices of quæstor, prætor, and tribune of the people, finally attaining to the consulship, 100 A.D. His inaugural address to the emperor Trajan, a long and finished but rather pedantic oration in Ciceronian

¹ Three books, in six volumes, were entitled "Studiosus," and eight books bore the title "Dubius Sermo." To this last he probably refers, *Præf.* § 28, "audio—Epicureos quoque parturire adversus libellos quos de grammatica edidi."

² Bellorum Germaniæ viginti (libri), quibus omnia quæ cum Germanis gessimus bella collegit (Pliny, *Ep.* iii. 5, § 4). A treatise on throwing the lance from horseback, "De jaculatione equestri," is mentioned here as his first work, written when he was in command of a squadron of cavalry (præfectus alæ).

³ Pliny, *Ep.* iii. 5, § 16; see *ibid.* §§ 8-10.

⁴ *Epist.* vi. 16, § 13.

⁵ "Quid agit Comum, tuæ meæque deliciæ?" he writes to Caninius Rufus, *Ep.* i. 3. He had several country houses on this estate (plures villæ, *Ep.* ix. 7). Two of these, his especial favourites, he playfully called "Tragedy and Comedy," comparing the low and the lofty site to the *soccus* and the *cothurnus* of the actors.

⁶ Pliny speaks of him with great regard in ii. 1, § 8:—"Ille mihi tutor relictus adfectum parentis exhibuit."

⁷ His motto was "to pardon others as if one daily needed pardon oneself, and to abstain from sins as if one viewed sin as unpardonable," viii. 22. In *Ep.* 2 of the same book he finely says, "Mihi egregium in primis videtur, ut foris ita domi, ut in magnis ita in parvis ut in alienis ita in suis, agitare justitiam."

Latinity, entitled *Panegyricus*, is extant.¹ "The good old custom," he says in his opening sentence, "of commencing all public business with prayers to the gods is especially to be observed by a consul, and on an occasion of offering public thanks to the best of princes by the command of the senate and the state." The piece teaches us a good deal about the imperial policy and the military career of Trajan (§§ 13-16).

Between Pliny and Trajan the sincerest regard and even affection seem to have subsisted. In the last book of the *Epistles*, which contains a hundred and twenty-one letters and replies on matters of business connected with the province between Pliny and the emperor, the latter is always addressed as "Domine" (sire), the former as "Secunde (or mi Secunde) carissime." Most of these were written by Pliny as *proprætor* (103-5) of Bithynia and Pontica, and they show the careful interest taken in the welfare and prosperity of the cities under his charge. The replies of the emperor are characteristically brief; they are written in good and literary Latin, and show Trajan to have been a man of letters as well as a man of business. Pliny's celebrated inquiry what should be done with recusant Christians, in which he says² that "not only cities but country towns and rural districts have been touched by the contagion of this superstition," is briefly replied to; "conquirendi non sunt," writes the emperor, "si deferantur et arguantur, puniendi sunt, ita tamen ut qui negaverit se Christianum esse, idque re ipsa manifestum fecerit, id est supplicando dis nostris, quamvis suspectus in præteritum, veniam ex poenitentia impetret." Pliny had said:—"Those who obstinately persisted that they were Christians, after being warned of the consequence, I ordered to be led off to punishment, not doubting that, whatever it was that they professed, their inflexible obstinacy deserved it." Doubts have even been raised as to the genuineness of a passage which appears so inconsistent with the established Roman policy of tolerating every *superstitio*. But it is clear that what Pliny doubted was the fidelity to the emperor of those who refused to make the customary religious offerings to his statue. It was zeal for loyalty that led him into a course which his humane nature condemned.³

Pliny was twice married, but had no children. The emperor bestowed on him the *jus trium liberorum*, which conferred certain state privileges upon those who brought up that number of legitimate children to become Roman citizens. Three affectionate letters, none of them long, are addressed to his second wife Calpurnia Hispulla.

In health Pliny seems to have been far from robust. He speaks of his slight and thin figure, "*gracilitas mea*,"⁴ though in his youth he had seen military service in the East.⁵ He was fond too of hunting, but used to boast that he combined the worship of Diana with that of Minerva.⁶

Pliny's great wealth was most liberally bestowed, both privately and publicly. He undertakes to rebuild a temple of Ceres on his estate, entirely at his own cost, with a

new statue and the addition of a portico, with walls and floor decorated with marbles.⁷ To his friend Romatius Firmus, a fellow-townsmen, he writes⁸ that in order to have the pleasure of seeing him an *eques* he offers £2500 to make up the equestrian census. To Calpurnia, in addition to nearly £1000 which he had given her as a marriage portion, he offers to remit the whole of the mortgage debt on an encumbered estate which she had inherited from her father. He founded⁹ and endowed with landed property an almshouse for people of free birth of both sexes.¹⁰ He presented his nurse with a farm worth nearly £1000;¹¹ he gave fifty sesteria¹² as a marriage present to the daughter of his tutor Quintilian; he gave up to the township of Comum a sum of about £3500, which, having been illegally left to it by Saturninus, Pliny, as his heir, could have claimed for himself,—and this in addition to over £10,000, which he had already given to the same township. He generously returned a large percentage of the sum he had sold his vintage for, when the produce had been found to disappoint the purchasers.¹³ In a beautiful letter to Sabinianus¹⁴ he kindly intercedes for a *libertus* with whom his friend was offended. In a word, the letters are full of acts of Pliny's goodness and generosity, and these are not boastfully expressed, but rather with the view of inciting others by his example.

There are few, if indeed any, remains of Roman prose literature which are as elegant, as interesting, and as varied as Pliny's *Letters*. They were evidently written and published¹⁵ on the model and precedent of Cicero's *Letters*. They are all carefully composed, and couched in the most graceful and polished Latinity. The first letter is a reply to a friend, Septicius, who had often requested Pliny to collect and publish his more carefully written correspondence,—"*si quas paulo curatius scripsisset*." An admirer of nature, and with the faculty for observation perhaps learnt from his uncle, he sometimes describes, and in the most beautiful language, the scenes or wonders he had visited.¹⁶ Of his spacious and beautiful villas in Tuscany and at Laurentum he has given full and detailed accounts, which are of especial value as almost the sole authority on the difficult subject of Roman houses.¹⁷ The Tuscan estate appears to have been his favourite residence. In reply to his friend Fuscus (ix. 36) he gives a pleasing account of the daily life and studies of a refined and temperate man, and a considerate country gentleman, neighbour, and landlord. Of the eruption of Vesuvius in 79 A.D., and the death of his uncle, he gives a minute and evidently faithful account as an eye-witness. This is contained in two long letters¹⁸ to his friend Tacitus the historian. Two excellent ghost-stories are given,¹⁹ and a letter to Tacitus on the omens of dreams²⁰ shows that both the friends had considerable credulity on this subject.

Like Cicero, but not so frequently, Pliny occasionally²¹ "ventilates" his Greek, and he tells us that at the age of fourteen he wrote a Greek tragedy, adding jocosely, "*qualem? inquis: nescio; tragœdia vocabatur*" (vii. 4, § 2). Like Cicero too, he was fond of art; he describes with enthusiasm²² a Corinthian bronze statuette which he had just purchased out of a legacy received.

As a writer Pliny the younger is as graceful, fluent, and polished as the style of the elder Pliny is crabbed and obscure. Indeed, the Latinity of the epistles cannot fairly be called inferior to that of Cicero himself. There are few indications of the "deterioration"

⁷ ix. 39. A similar offer is made to Trajan, including the dedication of his statue, *Ep. Pl. et Tr.*, 8.

⁸ i. 19.

⁹ vii. 18.

¹⁰ vi. 3.

¹¹ About £430, vi. 32.

¹² viii. 2.

¹³ ix. 21. "Tunc præcipua mansuetudinis laus," he well says, "cum ire causa justissima est."

¹⁴ Keil (*Præf.* to ed. Teubner, 1865, p. 1) quotes Sidonius Apollinaris, *Epist.* ix. 1, to show that nine books of his *Letters* were edited by Pliny himself.

¹⁵ E.g., the sources of the Clitumnus, viii. 8, and the floating islands on a lake at Ameria, viii. 20.

¹⁶ See ii. 17 and v. 6. The former describes in glowing terms the Laurentian villa, though he says of it in iv. 6, "*nihil ibi possideo præter tectum et hortum, statimque harenas*"; but he is comparing the extent of other landed properties.

¹⁷ vi. 16 and 20.

¹⁸ vii. 27.

¹⁹ i. 18. It is clear from *Ann.* vi. 25 that Tacitus had some belief in astrology. Pliny the elder wrote his history of the German wars "*somnio monitus*," *Ep.* iii. 5, § 4.

²⁰ E.g. in i. 18 and 20; ii. 3; iv. 7; ix. 26.

²¹ iii. 6. He says, however (§ 1), that in bronzes he was not much of a critic: "in hac re certe perquam exiguum sapio."

¹ He alludes to it in iii. 13, and in iii. 18 he explains how the address in the senate was afterwards expanded into a book, and recited for three consecutive days to his friends. The title *Panegyricus* appears then to have been given to it.

² x. 96, § 9.

³ The context shows that he had some suspicion that the Christians were forming secret and illegal societies (*heteriæ*, § 8). This is his only excuse for having put two deaconesses (*ministrae*) to the torture, to find out what they really held.

⁴ ii. 11, § 15.

⁵ iii. 11, § 5.

⁶ ix. 10. In i. 6 he gives a droll account of his hunting wild boars, and reading books while the beaters were at work: "*ad retia sedebam; erat in proximo non venabulum aut lancea, sed stilus et pugilares; meditabar aliquid enotabamque, ut si manus vacuas plenas tamen ceras reportarem*."

(if progress and development in a language ought so to be called) of the "Silver Age." That he imitated Cicero both in his style and his eloquence is avowed by himself.¹ As a friend of Tacitus, whom he often mentions, he predicts the "immortality" of the books of his history, and he even proffered his services in reading Tacitus's MSS.² He writes also to Suetonius and to Cornelius Nepos, the latter of whom he speaks of as "vir gravissimus, doctissimus, disertissimus;" the former he praises to Trajan,³ in asking for him the *jus trium liberorum*, as "probiissimum honestissimum eruditissimum virum."

Pliny's *Epistles* were first printed in 1471, but incomplete, as was the Aldine edition of 1508. A full account of the MSS. and editions is given by H. Keil in his preface; among the best editions of later times are that of Curtius, published in 1734; after his death that of G. H. Schaefer (who reprinted with corrections, in 1805, the text of Gesner and Gierig, 1800), and that of Maurice Doering, 1843. The latest and best is the Teubner text of H. Keil (Leipzig, 1865, 12mo), with full indices and brief introductory notice of the most important different readings (F. A. P.)

PŁOCK (PŁOTSK), a government of Russian Poland, on the right bank of the Vistula, having the provinces of Western and Eastern Prussia on the north, and the Polish provinces of Łomża on the east and Warsaw on the south; its area is 4200 square miles. Its flat surface, 350 to 500 feet above the sea-level, gently rises towards the north, where it merges in the Baltic coast-ridge of the Prussian lake district. Only a few hills reach 600 feet above the sea, while the broad valley of the Vistula has an elevation of but 130 to 150 feet. In the west—district of Lipno—broad terraces covered with forests, small lakes, and ponds, and very poor in vegetation, descend from the Baltic lake-district towards the plains of Płock; and in the central district of Mława extensive marshes cover the upper basin of the Wkra. The Vistula borders the province on the south, almost from Warsaw to Thorn, receiving the Skrwia and Wkra, which last rises on the Prussian frontier, and, flowing south-east, joins the Narew close to its confluence with the Vistula, in the south-eastern corner of Płock. The Drwęca, or Drewenz, flows along the north-west boundary of Płock, while several small tributaries of the Narew water the north-eastern district of Ciechanow. Petty lakes and ponds dot the plains in the west, and the whole country bears traces of a very wide extension of lakes during the post-Glacial period. Peat-bogs, used of late for fuel, and marshes containing bog-iron, fill many depressions in the north, while the more elevated parts of the plains are covered with fertile clays, or a kind of "black-earth." Lacustrine post-Glacial deposits cover all depressions in the thick sheet of boulder clay, with Scandinavian erratic boulders, which extends everywhere over the Tertiary sands and marls,—these last containing masses of silicated wood and lignite. Layers of gypsum are found in the hills on the Vistula. The soil is very fertile in several parts of the province, especially in the district of Lipno and closer to the Vistula, and agriculture is the chief occupation of the inhabitants even in the towns. The chief crops are, however, rye, oats, and barley; but wheat gives good crops in some parts of the province; beet-root is also cultivated for sugar, especially on the great estates of the west, where machinery finds application to agriculture on a large scale; in the north the property is much divided, and the *szlachta*-landholders, very numerous in Ciechanow, are far from prosperous. The average crops of late years may be valued at 1,700,000 quarters of corn and 1,575,000 quarters of potatoes. The forests, which formerly covered very extensive tracts, are much destroyed now, but still Płock is one of the best wooded provinces of Poland.

The population of the province of Płock, which was but 490,950 in 1873, reached 538,150 in 1881, and must be now about 557,000. It is Polish throughout, but contains a large admixture of Jews (more than 11 per cent.) and of Germans, the number of whom is yearly increasing. Besides agriculture, the inhabitants find a per-

manent source of occupation in shipping on the Vistula, some mining, and various domestic trades, such as the fabrication of wooden cars, sledges, and wheels, and textile industry. The whole value of manufactures in 1879 was £211,000 (flour mills £68,900, saw-mills £17,500, sugar works £45,700, and iron works £32,200), and 1750 hands were employed. There is some export trade, especially in the Lipno district; but its development is limited by the lack of facilities of communication, the best being those offered by the Vistula. The railway from Warsaw to Dantzic, *via* Ciechanow and Mława, will now help the eastern part of the province.

Since the Prussian occupation, and perhaps under the influence of Prussian neighbourhood, the province of Płock is somewhat better supplied with primary schools, especially in its northern districts, than other provinces of Poland; still there are only 272 primary schools (exclusive of the Jewish *heders*), with 15,000 scholars. There are two colleges for boys and girls, and one seminary for teachers at Wymysły.

The province is divided into eight districts, the chief towns of which are Płock (22,140 inhabitants), Ciechanow (5800), Lipno (5650), Mława (10,050), Płońsk (6350), Przasnysz (7200), Rypin (3350), and Sierpce (6850). Novogeorgievsk, or Modlin, on the Vistula, 12 miles below its confluence with the Narew, is a fortress of the first rank; Wyszogrod (4400) has considerable trade in corn.

History.—After the second dismemberment of Poland in 1793, what is now the government of Płock became part of Prussia. It fell under Russian dominion after the treaty of Vienna, and, in the division of that time into five provinces, extended over the western part of the present province of Łomża, which was created in 1864 from the Ostrolenka and Pultusk districts of Płock together with parts of the province of Augustowo.

PŁOCK, capital of the above province, is situated on the right bank of the Vistula, 60 miles to the west-north-west of Warsaw. It is well built of stone on a high hill facing the river, and has an ancient cathedral. It is now of importance only as the seat of the provincial administration; and its population, which is partly agricultural, increases very slowly. In May 1883 it had 19,640 inhabitants, of whom 7135 were Jews and about 450 Germans. The Russian garrison numbered 2500. Płock has two colleges for boys and girls, with 864 male and 496 female scholars, and twelve primary schools (exclusive of the Jewish *heders*), with 890 scholars. Its manufactures are insignificant (not above 100,000 roubles yearly), and there is some trade in agricultural produce.

PLOTINUS. See **NEOPLATONISM**, vol. xvii. p. 335 *sq.*

PLOUGH. See **AGRICULTURE**, vol. i. p. 311.

PLOVER, French *Pluvier*, Old French *Plovier*, which doubtless has its origin in the Latin *pluvia*, rain (as witness the German equivalent *Regenpfeifer*, Rain-fifer); but the connexion of ideas between the words therein involved, so that the former should have become a bird's name, is doubtful. Belon (1555) says that the name *Pluvier* is bestowed "pour ce qu'on le prend mieux en temps pluvieux qu'en nulle autre saison," which is not in accordance with modern observation, for in rainy weather Plovers are wilder and harder to approach than in fine. Others have thought it is from the spotted (as though with rain-drops) upper plumage of two of the commonest species of Plovers, to which the name especially belongs—the *Charadrius pluvialis* of Linnæus, or Golden Plover, and the *Squatarola helvetica* of recent ornithologists, or Grey Plover. Both these birds are very similar in general appearance, but the latter is the larger and has an aborted hind-toe on each foot.⁴ Its axillary feathers are also black, while in the Golden Plover they are pure white, and this difference often affords a ready means of distinguishing the two species when on the wing, even at a considerable distance. The Grey Plover is a bird of almost circumpolar range, breeding in the far north of America, Asia, and eastern Europe, frequenting in spring and autumn the coasts of the more temperate parts of each continent, and generally retiring further southward in winter—examples

¹ Cf. i. 5, § 12; iv. 8, § 4.

² See vii. 20; viii. 7; viii. 33, § 1; ix. 14.

³ *Ep. Pl. et Traj.*, 94.

⁴ But for this really unimportant distinction both birds could doubtless have been kept by ornithologists in the same genus, for they agree in most other structural characters. As it is they have long been sundered.

not unfrequently reaching the Cape Colony, Ceylon, Australia, and even Tasmania. *Charadrius pluvialis* has a much narrower distribution, though where it occurs it is much more numerous as a species. Its breeding quarters do not extend further than from Iceland to western Siberia, but include the more elevated tracts in the British Islands, whence in autumn it spreads itself, often in immense flocks, over the cultivated districts if the fields be sufficiently open. Here some will remain so long as the absence of frost or snow permits, but the majority make for the Mediterranean basin, or the countries beyond, in which to winter; and, as with the Grey Plover, stragglers find their way to the southern extremity of Africa. The same may be said, *mutatis mutandis*, of what are usually deemed to be two other cognate forms, *C. virginicus* and *C. fulvus*, which respectively represent *C. pluvialis* in America and eastern Asia, where they are also known by the same English name. The discrimination of these two birds from one another requires a very acute eye, and room is here wanting in which to specify the minute points in which they differ;¹ but both are easily distinguished from their European ally by their smaller size, their greyish-brown axillary feathers, and their proportionally longer and more slender legs. All, however,—and the same is the case with the Grey Plover,—undergo precisely the same seasonal change of colour, greatly altering their appearance and equally affecting both sexes. In the course of spring or early summer nearly the whole of the lower plumage from the chin to the vent, which during winter has been nearly pure white, becomes deep black. This is partly due to the growth of new feathers, but partly to some of the old feathers actually changing their colour, though the way in which the alteration is brought about is still uncertain.² A corresponding alteration is at the same season observable in the upper plumage; but this seems chiefly due (as in many other birds) to the shedding of the lighter-coloured margins of the feathers, and does not produce so complete a transformation of appearance, though the beauty of the wearer is thereby greatly increased.

Though the birds just spoken of are those most emphatically entitled to be called Plovers, the group of Ringed Plovers before mentioned (KILLDEER, vol. xiv. p. 76) and the LAPWING (vol. xiv. p. 308), with its allies, have, according to usage, hardly less claim to the name, which is also extended to some other more distant forms that can here have only the briefest notice. Among them one of the most remarkable is the "Zickzack" (so called from its cry)—the *τροχίλος* of Herodotus (see HUMMING-BIRD, vol. xii. p. 358, n. 3), the *Pluvianus* or *Hya ægyptius* of ornithologists, celebrated for the services it is said to render to the crocodile—a small bird whose plumage of delicate lavender and cream-colour is relieved by markings of black and white. This probably belongs to the small section generally known as Coursers, *Cursorius*, of which some eight or ten species inhabit the deserts of Africa and India, while one, *C. gallicus*, occasionally strays to Europe and even to England. Allied to them are the curious PRATINCOLES (*q.v.*), also peculiar to the Old World, while

the genera *Thinocoris* and *Attagis* form an outlying group peculiar to South America, that is by some systematists regarded as a separate Family *Thinocoridae*, near which are often placed the singular SHEATHBILLS (*q.v.*). By most authorities the Stone-Curlews (CURLEW, vol. vi. p. 712), the OYSTER-CATCHERS (vol. xviii. p. 111), and TURNSTONES (*q.v.*) are also regarded as belonging to the Family *Charadriidae*, and some would add the Avocets (*Recurvirostra*) and STILTS (*q.v.*), among which the Cavalier, *Dromas ardeola*—a form that has been bandied about from one Family and even Order to another—should possibly find its resting-place. It frequents the sandy shores of the Indian Ocean and Bay of Bengal from Natal to Aden, and thence to Ceylon, the Malabar coast, and the Andaman and Nicobar Islands,—a white and black bird, mounted on long legs, with webbed feet, and a bill so shaped as to have made some of the best ornithologists lodge it among the TERNS (*q.v.*).

Though the various forms here spoken of as Plovers are almost certainly closely allied, they must be regarded as constituting a very indefinite group, for hardly any strong line of demarcation can be drawn between them and the SANDPIPERS and SNIPES (*q.v.*). United, however, with both of the latter, under the name of *Limicola*, after the method approved by the most recent systematists, the whole form an assemblage the compactness of which no observant ornithologist can hesitate to admit, even if he be not inclined to treat as its nearest relations the Bustards on the one hand and the *Gaviæ* on the other, as before suggested (ORNITHOLOGY, vol. xviii. p. 45). (A. N.)

PLÜCKER, JULIUS (1801–1868), mathematician and physicist, was born at Elberfeld on the 16th June 1801. After being educated at the gymnasium at Düsseldorf and studying at the universities of Bonn, Heidelberg, and Berlin, he went in 1823 for a short time to Paris, where he came under the influence of the great school of French geometers, whose founder, Monge, was only recently dead; and there can be no doubt that his intercourse with the mathematicians of that school, more particularly with Poncelet and Gergonne, greatly helped to determine the earlier part at least of his career. In 1825 he was received as "privat-docent" at Bonn, and after three years he was made professor extraordinary. The title of his "habilitationsschrift," *Generalem analyseos applicationem ad ea quæ geometriæ altioris et mechanicæ basis et fundamenta sunt e serie Tayloria deducit Julius Plücker* (Bonn, 1824), indicated the course of his future researches. The mathematical influence of Monge had two sides represented respectively by his two great works, the *Géométrie Descriptive* and the *Application de l'Analyse à la Géométrie*. Although fully master of those general ideas of modern geometry whose development began with the publication of the former of these works, Plücker's actual labours lay more in the direction of the latter. It was his aim to furnish modern geometry with suitable analytical methods and thus to give it an independent analytical development. In this effort he was as successful as were his great contemporaries Poncelet and Steiner in cultivating geometry in its purely synthetical form. From his lectures and researches at Bonn sprang his first great work *Analytisch-Geometrische Entwicklungen* (vol. i. 1828, vol. ii. 1831).

In the first volume of this treatise Plücker introduced for the first time³ the method of abridged notation which has become one of the characteristic features of modern analytical geometry. The peculiarity of this method consists in this, that the letters used in the equations of curves and surfaces represent, not coordinates of a point with respect to arbitrary chosen axes, but straight lines, or it may be curves or surfaces, intrinsically related to the figure

¹ Schlegel (*Mus. Pays-Bas, Cursores*, p. 53) states that in some examples it seems impossible to determine the form to which they belong; but ordinarily American specimens are rather larger and stouter, and have shorter toes than those from Asia.

² It is much to be regretted that ornithologists favourably situated in regard to zoological gardens have not more extensively used opportunities which might thus be accorded to them of conducting useful observations on this subject and others of similar kind. Elsewhere it would be hardly possible to carry on such an investigation, and even under the best circumstances it would not be easy and would require unremitting attention. The results of some partial observations superintended by Yarrell in the gardens of the Zoological Society of London are given in its *Transactions* (i. pp. 13–19). Little has been done there since of this nature.

³ The independent development of a similar idea by the brilliant young French geometer Bobillier (1797–1832) was cut short by his premature death.

under discussion. For example, if it be wished to investigate the properties of a conic section with respect to a pair of tangents and their chord of contact, we write its equation $uv + w^2 = 0$, where $u = 0$, $v = 0$, $w = 0$ represent the two tangents and the chord of contact respectively. This procedure has two great advantages. It enables us to greatly abridge the necessary analytical equations, to arrive at them more easily, and thus to lighten or altogether avoid the cumbersome algebraical calculations which had broken the back of the old-fashioned Cartesian geometry and arrested its progress altogether; and it greatly facilitates the geometrical interpretation of analytical results whether intermediate or final. In the first volume of the *Entwickelungen*, Plücker applied the method of abridged notation to the straight line, circle, and conic sections, and he subsequently used it with great effect in many of his researches, notably in his theory of cubic curves.

In the second volume of the *Entwickelungen*, Plücker clearly established on a firm and independent basis the great principle of duality. This principle had originally been established by Poncelet as a corollary on the theory of the pole and polar of a conic section. Gergonne maintained the independent and fundamental nature of the principle, and hence arose a violent discussion between him and Poncelet into which Plücker was drawn. He settled the matter in Gergonne's favour by introducing the notion of the coordinates of a line and of a plane, and showing that in plane geometry, for example, we could with equal readiness represent a point either by means of coordinates or by means of an equation, and that the same was true of a line. Hence it appeared that the point or the line in plane geometry, and the point or the plane in solid geometry, could with equal readiness and with equal reason be taken as elements. It was thus made evident that any system of equations proving a theorem regarding points and lines or regarding points and planes could at once be read as proving another in which the words *point* and *line* or the words *point* and *plane* were everywhere interchanged.

Another subject of importance which Plücker took up in the *Entwickelungen* was the curious paradox noticed by Euler and Cramer, that, when a certain number of the intersections of two algebraical curves are given, the rest are thereby determined. Gergonne had shown that when a number of the intersections of two curves of the $(p+q)$ th degree lie on a curve of the p th degree the rest lie on a curve of the q th degree. Plücker finally (*Gergonne Ann.*, 1828-29) showed how many points must be taken on a curve of any degree so that curves of the same degree (infinite in number) may be drawn through them, and proved that all the points, beyond the given ones, in which these curves intersect the given one are fixed by the original choice. Later, simultaneously with Jacobi, he extended these results to curves and surfaces of unequal order. Allied to the matter just mentioned was Plücker's discovery of the six equations connecting the numbers of singularities in algebraical curves. It will be best described in the words of Clebsch:—"Cramer was the first to give a more exact discussion of the singularities of algebraical curves. The consideration of singularities in the modern geometrical sense originated with Poncelet. He showed that the class k of a curve of the n th order, which Gergonne by an extraordinary mistake had considered to be identical with its order, is in general $n(n-1)$; and hence arose a paradox whose explanation became possible only through the theory of the simple singularities. By the principle of duality the order n of a curve should be derived in the same way from the class k as k is from n . But if we derive n in this way from k we return not to n but to a much greater number. Hence there must be causes which effect a reduction during this operation. Poncelet had already recognized that a double point reduces the class by 2, a cusp at least by 3, and a multiple point of the p th order, all of whose tangents are distinct, by $\frac{1}{2}p(p-1)$. Here it was that Plücker took up the question. By first directly determining the number of the points of inflexion, considering the influence of double points and cusps, and finally applying the principle of duality to the result obtained, he was led to the famous formulæ for the singularities of curves which bear his name, and which completely resolve the paradox of Poncelet—formulæ which already in the year 1854 Steiner could cite as the 'well known,' without, however, in any way mentioning Plücker's name in connexion with them. Plücker communicated his formulæ in the first place to *Crelle's Journal*, vol. xii. (1834), and gave a further extension and complete account of his theory in his *Theorie der Algebraischen Curven*, 1839."

In 1833 Plücker left Bonn for Berlin, where he occupied for a short time a post in the Friedrich Wilhelm's Gymnasium. He was then called in 1834 as ordinary professor of mathematics to Halle. While there he published his *System der Analytischen Geometrie, auf neue Betrachtungsweisen gegründet, und insbesondere eine Ausführliche Theorie der Curven dritter Ordnung enthaltend*, Berlin, 1835. In this work he introduced the use of linear functions in place of the ordinary coordinates, and thereby increased the generality

and elegance of his equations; he also made the fullest use of the principles of collineation and reciprocity. In fact he develops and applies to plane curves, mainly of the third degree, the methods which he had indicated in the *Entwickelungen* and in various memoirs published in the interim. His discussion of curves of the third order turned mainly on the nature of their asymptotes, and depended on the fact that the equation to every such curve can be put into the form $pqr + \mu s = 0$. He gives a complete enumeration of them, including two hundred and nineteen species. In 1836 Plücker returned to Bonn as ordinary professor of mathematics. Here he published his *Theorie der Algebraischen Curven* which formed a continuation of the *System der Analytischen Geometrie*. The work falls into two parts, which treat of the asymptotes and singularities of algebraical curves respectively; and extensive use is made of the method of counting constants which plays so large a part in modern geometrical researches. Among the results given we may mention the enumeration of curves of the fourth order according to the nature of their asymptotes, and according to the nature of their singularities, and the determination for the first time of the number of double tangents of a curve of the fourth order devoid of singular points.

From this time Plücker's geometrical researches practically ceased, only to be resumed towards the end of his life. It is true that he published in 1846 his *System der Geometrie des Raumes in neuer Analytischer Behandlungsweise*, but this contains merely a more systematic and polished rendering of his earlier results. It has been said that this cessation from pure mathematical work was due to the inappreciative reception accorded by his countrymen to his labours, and to their jealousy of his fame in other lands; it seems likely, however, that it was due in some degree to the fact that he was called upon to undertake the work of the physical chair at Bonn in addition to his proper duties. In 1847 he was made actual professor of physics, and from that time his wondrous scientific activity took a new and astonishing turn.

Plücker now devoted himself to experimental physics in the strictest sense as exclusively as he had formerly done to pure mathematics, and with equally brilliant results. His first physical memoir, published in *Poggendorff's Annalen*, vol. lxxii., 1847, contains his great discovery of magnecrystalline action. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. It is unnecessary here to analyse these researches, of which an account has been given in the article *MAGNETISM* (vol. xv. p. 262 sq.); it will be sufficient to say that in this work Plücker was the worthy collaborateur, and, had it not been that their fast friendship and mutual admiration renders the word inappropriate, we might have said rival, of Faraday.

In 1858 (*Pogg. Ann.*, vol. ciii.) he published the first of his classical researches on the action of the magnet on the electric discharge in rarefied gases (see *ELECTRICITY*, vol. viii. p. 74). It is needless now to dilate upon the great beauty and importance of these researches, which remain the leading lights in one of the darkest channels of magnetic science. All the best work that has recently been done on this important subject is simply development of what Plücker did, and in some instances (notably in many of the researches of Crookes) merely reproduction on a larger scale of his results.

Plücker, first by himself and afterwards in conjunction with Hittorf, made many important discoveries in the spectroscopy of gases. He was the first to use the vacuum tube with the capillary part now called a Geissler's tube,

by means of which the luminous intensity of feeble electric discharges was raised sufficiently to allow of spectroscopic investigation. He anticipated Bunsen and Kirchhoff in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them, and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy. For a fuller account of the important discoveries regarding the influence of temperature and pressure on the nature of gaseous spectra made in conjunction with Hittorf see SPECTRUM ANALYSIS.

Hittorf, who had good means of knowing, tells us that Plücker never attained great manual dexterity as an experimenter. He had always, however, very clear conceptions as to what was wanted, and possessed in a high degree the power of putting others in possession of his ideas and rendering them enthusiastic in carrying them into practice. Thus he was able to procure from the Sayner Hütte in 1846 the great electromagnet which he turned to such noble use in his magnetic researches; thus he attached to his service his former pupil the skilful mechanic Fessel; and thus he discovered and fully availed himself of the ability of the great glass-blower Geissler, in conjunction with whom he devised many of those physical instruments whose use all over the civilized world has rendered the name of the artificer of Bonn immortal. It was thus also that, when he felt his own want of chemical knowledge and manipulative skill, he sought and obtained the assistance of Hittorf, one of the ablest of German experimenters.

Induced by the encouragement of his mathematical friends in England, Plücker in 1865 returned once more to the field in which he first became known to fame, and adorned it by one more great achievement—the invention of what is now called Line Geometry. A remark containing the fundamentally new idea of this new geometry had, as Clebsch remarks, already been embodied in the *System der Geometrie des Raumes*:—"A straight line depends on four linear constants. The four magnitudes which we consider as variables receive for any given line constant values, which may be easily constructed and are the four coordinates of the straight line. A single equation between these four coordinates does not determine a locus for the straight line, but merely a law according to which infinite space is made up of straight lines." Here we have the new idea of the straight line considered as an element of space, and of the "complex," as Plücker afterwards called it, made up of a threefold infinity of straight lines subject to a onefold relation. Space thus becomes as it were four-dimensioned, and we have, instead of the three degrees of freedom of space considered as an aggregate of points, four degrees of freedom according as the linear element is (1) absolutely unconditional, (2) subject to a onefold, (3) subject to a twofold, or (4) subject to a threefold relation. In the first case we have the complex of straight lines, in the second the congruency of lines, in the third the regulus or ruled surface. The last of these geometrical figures had been considered long before, and even the congruency had been discussed before or independently of Plücker, notably by Hamilton and Kummer. The general conception of the linear complex seems to be entirely due to Plücker. At all events he developed the notion to such an extent that he is entitled to be called the founder of Line Geometry, in which the theory of the complex holds a fundamental position. His first memoir on the subject was published in the *Philosophical Transactions* of the Royal Society of London. It attracted much attention,

and almost at once became the source of a large literature in which the new science was developed. Plücker himself worked out the theory of complexes of the first and second order, introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now so well known to the student of the higher mathematics. He was engaged in bringing out a large work embodying the results of his researches in Line Geometry when he died on the 22d May 1868. The work was so far advanced that his pupil and assistant Klein was able to complete and publish it, thereby erecting the worthiest monument to the genius of his master, whose wonderful scientific activity endured to the very last. Of the very numerous honours bestowed on Plücker by the various scientific societies of Europe it may suffice to mention here the Copley medal, awarded to him by the Royal Society two years before his death.

Most of the facts in the above notice have been taken from Clebsch's obituary notice of Plücker (*Abh. d. Kön. Ges. d. Wiss. z. Göttingen*, xvi., 1871), to which is appended an appreciation of Plücker's physical researches by Hittorf, and a list of Plücker's works by F. Klein. See also Gerhardt, *Geschichte der Mathematik in Deutschland*, p. 282; and Plücker's life by Dronke (Bonn, 1871).

PLUM (*Prunus*). Our cultivated plums are supposed to have originated from one or other of the species *P. domestica* or *P. insititia*. The young shoots of *P. domestica* are glabrous, and the fruit oblong; in *P. insititia* the young shoots are pubescent, and the fruit more or less globose. A third species, the common sloe or blackthorn, *P. spinosa*, has stout spines; its flowers expand before the leaves; and its fruit is very rough to the taste, in which particulars it differs from the two preceding. These distinctions, however, are not maintained with much constancy. *P. domestica* is a native of Anatolia and the Caucasus, and is considered to be only naturalized in Europe. *P. insititia*, on the other hand, is wild in southern Europe, in Armenia, and along the shores of the Caspian. In the Swiss lake-dwellings stones of the *P. insititia* as well as of *P. spinosa* have been found, but not those of *P. domestica*. Nevertheless, the Romans cultivated large numbers of plums. The cultivated forms are now extremely numerous, some of the groups, such as the green gages, the damsons, and the egg plums being very distinct, and even reproducing themselves from seed. This, however, cannot be depended on, and hence the choice varieties are propagated by budding or by layers. The colour of the fruit varies from green, pale yellow, red, up to deep purple, the size from that of a small cherry to that of a walnut; the form is oblong acute or obtuse at both ends or globular; the stones or kernels vary in like manner; and the flavour, season of ripening, and duration are all subject to variation. From its hardihood the plum is one of the most valuable fruit trees for the farmer, as it is not particular as to soil, and the crop is less likely to be destroyed by spring frosts. Prunes and French plums are merely plums dried in the sun. Their preparation is carried on on a large scale in Bosnia and Servia, as well as in Spain, Portugal, and southern France. The cherry plum, *Prunus myrobalana*, is employed chiefly as a stock for grafting upon, and for the sake of its ornamental flowers. See also HORTICULTURE, vol. xii. p. 275.

PLUMBAGO, a name frequently applied to graphite in allusion to its remote resemblance to lead, whence it is popularly called "black lead." When Scheele, in 1779, examined this mineral he regarded it as a compound of carbon and iron, and consequently termed it a "carburet of iron"; but Vanuxem in 1825 showed that the iron existed in the form of an oxide, and was not essential to the constitution of the mineral—a conclusion also reached about this time by Karsten. It thus became fully estab-

ished that plumbago is simply an impure form of native carbon. Plumbago is principally used in the manufacture of "black-lead" pencils, for which purpose it was at one time very extensively worked at Borrowdale in Cumberland. It was known locally as "wad," and a grant of the manor of Borrowdale, as far back as the reign of James I., refers to "the wad-holes and wad, commonly called black rawke." The Cumberland plumbago is found in pipes, strings, and irregular masses known as "sops," which occur in a dyke of diorite, associated with a compact blue diabase, penetrating some of the altered ash-beds of the volcanic series. Important mines of plumbago, yielding fine pencil lead, were opened some years ago by M. Alibert in the government of Irkutsk in eastern Siberia. A good deal of plumbago is also worked near Passau in Bavaria. The graphite so largely used, when mixed with fire-clay, in the manufacture of "black-lead" crucibles, is obtained chiefly from Ceylon; and it is notable that, notwithstanding the purity of the Ceylon plumbago, it is not applicable to the manufacture of lead pencils. Large quantities of plumbago occur in the Laurentian limestones of Canada; while in the United States the mineral is worked at Sturbridge, Mass.; at Ticonderoga and Fishkill, N.Y.; at Brandon, Vt.; and at Wake, N.C. It was formerly yielded by the mines of Ashford in Connecticut. Among the minor applications of plumbago may be mentioned its use as a lubricating agent for machinery and for polishing cast iron. In the preamble to an Act for protecting the black-lead mines of Cumberland, 25 Geo. II. c. 10, it is stated that plumbago is necessary "for divers useful purposes, and more particularly in the casting of bomb-shells, round shot, and cannon balls." It was formerly held in repute in medicine, and a writer on the Cumberland plumbago in 1709 asserts—"It's a present remedy for the cholick; it easeth the pain of gravel stone and strangury; and for these and the like uses it's much bought up by apothecaries and physicians." It is notable that plumbago is occasionally found in masses of meteoric iron, and that a substance of similar physical and chemical characters is produced in the blast-furnace during the preparation of cast iron, and is known to the workmen as *kish*. Plumbago bears a strong resemblance to the mineral termed molybdenite, while it resembles to a less extent certain varieties of micaceous iron-ore; the molybdenite, however, is easily distinguished by giving a slightly greenish streak, while the iron-ore yields a red streak.

For the mineralogical characteristics of plumbago or graphite, see vol. xvi. p. 381; for its chemical relations, vol. v. p. 86; and for its use in crucible-making, vol. ix. p. 843.

PLUNKET, WILLIAM CONYNGHAM PLUNKET, BARON (1765-1854), an eminent lawyer, orator, and statesman, was born in the county of Fermanagh in July 1765. He was educated in boyhood by his father, a man of considerable ability and reputation; and in 1779 he became a student of Trinity College, Dublin. Though well versed in regular academic studies, he was most conspicuous in his university career as the acknowledged leader of the Historical Society, the debating club of Trinity College, then full of young men of remarkable promise.

Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. His intellect was exactly that of a jurist or a great master of equity—not too refining or overprone to speculation, and yet capable of the highest legal generalizations, and of applying them to masses of fact, however tedious and complicated. His power of close and rapid argument was very remarkable, his memory equally capacious and exact, and he had enriched an ample store of professional learning with the fruits of assiduous general study. Although at first his progress at the bar was not rapid, he gradually obtained

a considerable practice in equity; and, after an apprenticeship of eleven years as a junior, he was raised to the rank of king's counsel in 1798.

In 1798 he entered the Irish parliament as member for Charlemont. His political faith was already settled, and was only slightly modified in after life, at least as regards its cardinal tenets. He was an anti-Jacobin Whig of the school of Burke, not ungracefully filled with a fervent Irish patriotism. He disliked the principles of the French Revolution, and its excesses made such an impression upon him that he always showed the greatest antipathy to merely democratic movements. But he was a sincere admirer of the constitutional government of England as established in 1688; he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was even in his youth the only reform he sought for his country; and, although he opposed the Union with all his power, this was only because he thought it incompatible with this object.

When Plunket became a member of parliament, the Irish Whig party was almost extinct, and Pitt was feeling his way to accomplish the Union. In this he was seconded ably by Lord Castlereagh, by the panic caused by a wild insurrection, and by the secession of Grattan from politics. When, however, the measure was actually brought forward, it encountered a vehement opposition; and among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognized. His speeches in these debates show all the force of reasoning, the admirable arrangement, and the grasp of facts which characterize his later efforts; but they are somewhat disfigured by personal invective, and here and there betray an indecent acrimony. They raised him, however, immediately to the front rank of his party; and, when Grattan re-entered the moribund senate, he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union of Great Britain and Ireland Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803, after the outbreak of Emmet's rebellion, he was selected as one of the crown lawyers to prosecute the unfortunate enthusiast, and at the trial, in summing up the evidence, delivered a speech of remarkable power, which shows his characteristic dislike of revolutionary outbursts. For this speech he was exposed to much unmerited obloquy, and more especially to the abuse of Cobbett, against whom he brought a successful action for damages. In 1804, in Pitt's second administration, he became solicitor-general and then attorney-general for Ireland; and he continued in office when Lord Grenville came into power at the head of the ministry of All the Talents. Plunket held a seat in the imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but, when the Grenville cabinet was dissolved, he returned once more to professional life, and for some years devoted himself exclusively to it.

In 1812, having amassed a considerable fortune, he re-entered parliament as member for Trinity College, and identified himself thoroughly with the Grenville or anti-Gallican Whigs. He was now in the full maturity of his powers, and very soon was acknowledged one of the first orators, if not the first, of the House of Commons. His reverence for the English constitution in church and state, his strong dislike of French principles, his steady advocacy of the war with Napoleon, and his antipathy to anything like democracy made him popular with the Tory party. On the other hand, he was the zealous and most able sup-

porter of Catholic emancipation; he was not averse to some measure of parliamentary reform; and, as generally he was on the side of constitutional progress, he was reckoned a principal ornament of one of the sections of the Whigs.

In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "bottle riot," an attempt on his part to put down the Orange faction in Ireland. But, though always the advocate of the Catholic claims, he strenuously opposed the Catholic Association, which about this time, under the guidance of O'Connell, began its extraordinary and successful agitation. He struggled vehemently to extinguish it, and in 1825 made a powerful speech against it; and thus the curious spectacle was seen of the ablest champion of an oppressed sect doing all in his power to check its efforts to emancipate itself.

In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who not unnaturally thought him an intruder, he was obliged to abandon this office. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. During this period he made some able speeches in favour of parliamentary reform; but they were scarcely equal to his earlier efforts; and his reputation as a judge, though far from low, was not so eminent as might have been expected. He died in 1854, in his ninetieth year. (w. o. m.)

PLUSH (French *Peluche*), a textile fabric having a cut nap or pile the same as fustian or velvet. Originally the pile of plush consisted of mohair or worsted yarn, but now silk by itself or with a cotton backing is used for plush, the distinction from velvet being found in the longer and less dense pile of plush. The material is largely used for upholstery and furniture purposes, and is also much employed in dress and millinery. The most distinctive form of plush is that which has taken the place of the napped beaver felt in the dress hats of gentlemen, which are now consequently known as "silk" hats. That plush, a considerable manufacture, is principally made in Lyons.

PLUTARCH (Πλούταρχος Χαιρωνεύς), a Greek prose writer, born at Chaeronea in Boeotia, and a contemporary of Tacitus and the Plinys. The precise dates of his birth and death are unknown; but it is certain that he flourished under the Roman emperors from Nero to Trajan inclusive, so that from 50 to 100 A.D. will probably include the best years of his life. There is some probability that he outlived Trajan,¹ who died in 117. In the *Consolation to his Wife* on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch's brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent to any particular school of philosophy. His forte, so to say, was learning, and the application of it to the casualties of human existence. His vast acquaintance with the literature of his time is everywhere apparent; and with history especially he was thoroughly conversant, and hardly less so with physics.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his forty-six *Parallel Lives*. He is thought to have written this work in his later years after

his return to his native town Chaeronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy,² though he says he was too much engaged in lecturing (doubtless in Greek, on philosophy) to turn his attention much to Roman literature during that period. Long observes that "we must expect to find him imperfectly informed on Roman institutions, and we can detect in him some errors. Yet, on the whole, his Roman lives do not often convey erroneous notions; if the detail is incorrect, the general impression is true."

Plutarch's design in writing the *Parallel Lives*—for this is the title which he gives them in dedicating *Theseus* and *Romulus* to Sosius Senecio—appears to have been the publication, in successive books, of authentic biographies in pairs, a Greek and a Roman (generally with some approximation to synchronism as well as some well-marked resemblances in political career) being selected as the subject of each. In the introduction to the *Theseus* he speaks of having already issued his *Lycurgus* and *Numa*, viewing them, no doubt, as bearing a resemblance to each other in their legislative character; and so *Theseus* and *Romulus* are compared as the legendary founders of states.

In the opening sentence of the life of Alexander he says that "in this book he has written the lives of Alexander and Cæsar" (Julius), and in his *Demosthenes*, where he again (§ 1) mentions his friend Sosius, Σόσιος, he calls the life of this orator and Cicero the fifth book.³ It may therefore fairly be inferred that Plutarch's original idea was simply to set (παραβάλλειν, *Nic.*, § 1) a Greek warrior, statesman, orator, or legislator side by side with some noted Roman celebrated for the same qualities. In his age, when Rome held the supremacy, but Greece was still looked up to as the centre and source of wisdom and art, such a comparison of the greatest men of both nations had a special propriety and significance, and was more than a mere literary exercise. It was a patriotic theme, to show the superiority of this or that race; and Plutarch, in a sense, belonged to both. Now Alexander and C. Cæsar, Demosthenes and Cicero, Solon and Valerius Publicola, have some fairly obvious resemblances, which are not so conspicuous in some other pairs. But the sequel which follows most (not all) of the *Lives*, entitled *σύγκρισις*, viz., a comparison in detail, is by modern critics rejected as spurious. It was manifestly added as an appendix from a misapprehension of Plutarch's real motive; the effort to bring out exact points of resemblances which are either forced or fanciful far exceeded the design contemplated by him. Moreover, the marked difference in style between the *βίοι* and the *συνκρίσεις* is quite decisive of the question.

Nearly all the lives are in pairs; but the series concludes with single biographies of Artaxerxes, Aratus (of Sicyon), Galba, and Otho. In the life of Aratus, not Sosius Senecio, but one Polycrates, is addressed.

It is not to be supposed that Plutarch was content to write merely amusing or popular biographies. On the contrary, the *Lives* are works of great learning and research, and they must for this very reason, as well as from their considerable length, have taken many years in their compilation. For example, in the life of *Theseus* the following long list of authorities appears:—the Megarian historians,⁴ Hellanicus, Simonides, Philochorus, Pherecydes, Demo, Pæon of Amathus, Dicearchus, Hero-

² *Demosth.*, § 2. Plutarch's orthography of Roman words and names is important as bearing on the question of pronunciation. A curious example (*De Fortun. Rom.*, § 5) is *Virtutis et Honoris*, written *Οὐρτοῦτῆς τε καὶ Ὁνῶρις*. The Volsci are *Οὐλοῦσχοι*, *ibid.*

³ It is quite evident that the original order of the books has been altered in the series of *Lives* as we now have them.

⁴ *Οἱ Μεγαράδων συγγραφῆς*, referred to in § 10.

¹ The scanty evidences of date collected from Plutarch's writings are well discussed by Long in *Smith's Dict. of Biog.*, iii. p. 429.

dorus, Bio, Menecrates, Clidemus, Hereas, Ister,¹ Diodorus. For the life of Romulus he refers to "one Promathio who composed a history of Italy" (§ 2 fin.), Diocles of Peparethus, Fabius Pictor, Herodorus, Varro, Valerius, Juba (Ἰόβας), Zenodotus of Trœzen, Simulus the poet (from whom he quotes eight elegiac verses), Antigonos, "one Butas,"² and Caius Acilius, and (as a *viva voce* informant) Sextius Sulla of Carthage. In the life of Lycurgus he cites Aristotle, Eratosthenes, Apollodorus, Timæus, Xenophon, Simonides, Aristocrates the Spartan, Sphærus, Critias, Theophrastus, Dioscorides, Hippias the sophist, Philostephanus, Demetrius Phalereus, Hermippus, Sosibius, Thucydides, Apollothemis, Aristoxenus, Aristocrates. In the life of Alexander, which is a long and elaborate essay, mention is made of Onesicritus, Aristobulus, Duris, Chares, Callisthenes, Eratosthenes, Clitarchus, Polyclitus, Antigeneis, Ister, Ptolemæus, Anticles, Philo of Thebes, Philippus of Theangele, Philippus of Eretria, Hecataeus, Hermippus, Sotion.

It is true that many of the lives, especially of Romans, do not show such an extent of research or such a wealth of authorities. But Plutarch must have possessed or had access to a great store of books, and his diligence as an historian cannot be questioned, if his accuracy is in some points impeached.

His sympathy with Doric characters and institutions is very evident; he delights to record the exploits, the maxims, and the virtues of Spartan kings and generals. This feeling is the key to his apparently unfair and virulent attack on Herodotus, who, as an Ionian, seemed to him to have exaggerated the prowess and the foresight of the Athenian leaders.
